

REPORT
OF THE
FIFTY-EIGHTH MEETING
OF THE,
BRITISH ASSOCIATION
FOR THE
ADVANCEMENT OF SCIENCE
HELD AT
BATH IN SEPTEMBER 1888.

LONDON:
JOHN MURRAY, ALBEMARLE STREET.
1889.

Office of the Association: 22 ALBEMARLE STREET, LONDON. W.

PRINTED BY
STODOLSKY AND CO., NEW-STREET SQUARE
LONDON

CONTENTS.

	Page
OBJECTS and Rules of the Association	xxvi
Places and Times of Meeting and Officers from commencement	xxxvi
Presidents and Secretaries of the Sections of the Association from commencement	xliv
List of Evening Lectures	lix
Lectures to the Operative Classes	lxii
Officers of Sectional Committees present at the Bath Meeting.....	lxiii
Officers and Council, 1888-89	lxv
Treasurer's Account	lxvi
Table showing the Attendance and Receipts at the Annual Meetings	lxviii
Report of the Council to the General Committee.....	lxx
Committees appointed by the General Committee at the Bath Meeting in September 1888	lxxiii
Synopsis of Grants of Money	lxxxii
Places of Meeting in 1889 and 1890	lxxxiii
General Statement of Sums which have been paid on account of Grants for Scientific Purposes	lxxxiv
Arrangement of the General Meetings	xcvi
Address by the President, Sir FREDERICK BRAMWELL, D.C.L., F.R.S., M.Inst.C.E.	1

REPORTS ON THE STATE OF SCIENCE.

Fourth Report of the Committee, consisting of Professors A. JOHNSON (Secretary), J. G. MACGREGOR, J. B. CHERRIMAN, and H. T. BOVEY and Mr. C. CARPMAEL, appointed for the purpose of promoting Tidal Observations in Canada	27
Report of the Committee, consisting of Sir R. S. BALL, Dr. G. JOHNSTONE STONEY, Professors EVERETT, FITZGERALD, HICKS, CAREY FOSTER, O. J. LODGE, ROYNTING, MACGREGOR, GENESE, W. G. ADAMS, and LAMB, Messrs. BAYNES, A. LODGE, FLEMING, W. N. SHAW, GLAZEBROOK, HAYWARD, LANT CARPENTER, CULVERWELL (Secretary), and GREENHILL, Dr. MUIR, and Messrs. G. GRIFFITH and J. LARMOR, appointed for the purpose of considering the desirability of introducing a Uniform Nomenclature for the Fundamental Units of Mechanics, and of co-operating with other bodies engaged in similar work.....	27

	Page
Fourth Report of the Committee, consisting of Professor BALFOUR STEWART (Secretary), Professor W. GRYLLS ADAMS, Mr. W. LANT CARPENTER, Mr. C. H. CARPMAEL, Mr. W. H. CHRISTIE (Astronomer Royal), Professor G. CHRYSTAL, Captain CREAK, Professor G. H. DARWIN, Mr. WILLIAM ELLIS, Sir J. H. LEFROY, Professor S. J. PERRY, Professor SCHUSTER, Professor Sir W. THOMSON, and Mr. G. M. WHIPPLE, appointed for the purpose of considering the best means of Comparing and Reducing Magnetic Observations	28
Fourth Report of the Committee, consisting of Professor G. FORBES (Secretary), Captain ABNEY, Dr. J. HOPKINSON, Professor W. G. ADAMS, Professor G. C. FOSTER, Lord RAYLEIGH, Mr. PREECE, Professor SCHUSTER, Professor DEWAR, Mr. A. VERNON HARCOURT, Mr. H. TRUEMAN WOOD, Sir JAMES DOUGLASS, Professor H. B. DIXON, and Mr. DIBDIN, appointed for the purpose of reporting on Standards of Light	39
Report of the Committee, consisting of Professor CRUM BROWN (Secretary), Mr. MILNE-HOME, Dr. JOHN MURRAY, Lord McLAREN, and Dr. BUCHAN, appointed for the purpose of co-operating with the Scottish Meteorological Society in making Meteorological Observations on Ben Nevis	49
Second Report of the Committee, consisting of Professors TILDEN, McLEOD, PICKERING, RAMSAY, and YOUNG and Drs. A. R. LEEDS and NICOL (Secretary), appointed for the purpose of reporting on the Bibliography of Solution	64
Report of the Committee, consisting of Professor G. CAREY FOSTER, Sir WILLIAM THOMSON, Professor AYRTON, Professor J. PERRY, Professor W. G. ADAMS, Lord RAYLEIGH, Dr. O. J. LODGE, Dr. JOHN HOPKINSON, Dr. A. MUIRHEAD, Mr. W. H. PREECE, Mr. HERBERT TAYLOR, Professor EVERETT, Professor SCHUSTER, Dr. J. A. FLEMING, Professor G. F. FITZGERALD, Mr. R. T. GLAZEBROOK (Secretary), Professor CHRYSTAL, Mr. H. TOMLINSON, Professor W. GARNETT, Professor J. J. THOMSON, Mr. W. N. SHAW, Mr. J. T. BOTTOMLEY, and Mr. T. GRAY, appointed for the purpose of constructing and issuing Practical Standards for use in Electrical Measurements	55
Second Report of the Committee, consisting of Professors TILDEN and W. CHANDLER ROBERTS-AUSTEN and Mr. T. TURNER (Secretary), appointed for the purpose of investigating the Influence of Silicon on the properties of Steel. (Drawn up by Mr. T. TURNER)	69
Third Report of the Committee, consisting of General J. T. WALKER, Sir WILLIAM THOMSON, Sir J. H. LEFROY, General R. STRACHEY, Professors A. S. HERSCHEL, G. CHRYSTAL, C. NIVEN, J. H. POYNTING (Secretary), and A. SCHUSTER, and Mr. C. V. BOYS, appointed for the purpose of inviting designs for a good Differential Gravity Meter in supersession of the pendulum, whereby satisfactory results may be obtained at each station of observation in a few hours instead of the many days over which it is necessary to extend pendulum observations.....	72
Report of the Committee, consisting of Professor H. E. ARMSTRONG, Mr. J. T. DUNN, Professor W. R. DUNSTAN (Secretary), Dr. J. H. GLADSTONE, Mr. A. G. VERNON HARCOURT, Mr. FRANCIS JONES, Professor H. McLEOD, Professor MELDOLA, Mr. PATTISON MUIR, Dr. W. J. RUSSELL, Mr. W. A. SHENSTONE, Professor SMITHELLS, and Mr. STALLARD, appointed for the purpose of inquiring into and reporting on the present methods of teaching Chemistry. (Drawn up by Professor DUNSTAN)	73
Report of the Committee, consisting of Dr. RUSSELL, Captain ABNEY, Professor HARTLEY, and Dr. A. RICHARDSON (Secretary), appointed for the investigation of the action of Light on the Hydracids of Halogens in presence of Oxygen. (Drawn up by Dr. A. RICHARDSON)	89
Second Report of the Committee, consisting of Professors TILDEN and	

CONTENTS.

	Page
RAMSAY and Dr. NICOL (Secretary), appointed for the purpose of investigating the Nature of Solution.....	93
Report of the Committee, consisting of Professor RAY LANKESTER, Mr. P. L. SCLATER, Professor M. FOSTER, Mr. A. SEDGWICK, Mr. WALTER HEAPE, Professor A. C. HADDON, Professor MOSELEY, and Mr. PERCY SLADEN (Secretary), appointed for the purpose of making arrangements for assisting the Marine Biological Association Laboratory at Plymouth.....	94
Third Report of the Committee, consisting of Professors TILDEN and ARMSTRONG (Secretary), appointed for the purpose of investigating Isomeric Naphthalene Derivatives. (Drawn up by Professor ARMSTRONG)	96
Third Report of the Committee, consisting of Dr. GARSON, Mr. PENGELLY, Mr. F. W. RUDLER, Mr. G. W. BLOXAM (Secretary), Mr. J. THEODORE BENT, and Mr. J. STUART GLENNIE, appointed for the purpose of investigating the Prehistoric Race in the Greek Islands	99
Report of the Committee, consisting of Sir RAWSON RAWSON, General PITT-RIVERS, Dr. MUIRHEAD, Mr. C. ROBERTS, Dr. J. BEDDOE, Mr. H. H. HOWORTH, Mr. F. W. RUDLER, Dr. G. W. HAMBLETON, Mr. HORACE DARWIN, Mr. G. W. BLOXAM, Dr. GARSON, and Dr. A. M. PATERSON, appointed for the purpose of investigating the effects of different occupations and employments on the Physical Development of the Human Body .	100
Sixteenth Report of the Committee, consisting of Professors J. PRESTWICH, W. BOYD DAWKINS, T. MCK. HUGHES, and T. G. BONNEY, Dr. H. W. CROSSKEY (Secretary), and Messrs. C. E. DE RANCE, H. G. FORDHAM, D. MACKINTOSH, W. PENGELLY, J. PLANT, and R. H. TIDDEMAN, appointed for the purpose of recording the position, height above the sea, lithological characters, size, and origin of the Erratic Blocks of England, Wales, and Ireland, reporting other matters of interest connected with the same, and taking measures for their preservation. (Drawn up by Dr. CROSSKEY, Secretary)	101
Report of the Committee, consisting of Professor VALENTINE BALL, Mr. H. G. FORDHAM, Professor HADDON, Professor HILLHOUSE, Mr. JOHN HOPKINSON, Dr. MACFARLANE, Professor MILNES MARSHALL, Mr. F. T. MOTT (Secretary), Dr. TRAQUAIR, and Dr. H. WOODWARD, reappointed at Manchester for the purpose of preparing a further Report upon the Provincial Museums of the United Kingdom.....	124
Second Report of the Committee, consisting of Mr. R. ETHERIDGE, Dr. H. WOODWARD, and Mr. A. BELL (Secretary), appointed for the purpose of reporting upon the 'Manure' Gravels of Wexford. (Drawn up by Mr. A. BELL)	133
Report of the Committee, consisting of Professors MCINTOSH (Secretary), ALLMAN, LANKESTER, BURDON SANDERSON, CLELAND, EWART, STIRLING, and MCKENDRICK, Drs. CLEGHORN and TRAQUAIR, for continuing the Researches on Food-Fishes at the St. Andrews Marine Laboratory	141
Fourteenth Report of the Committee, consisting of Drs. E. HULL and H. W. CROSSKEY, Sir DOUGLAS GALTON, Professor G. A. LEBOUR, and Messrs. JAMES GLAISHER, E. B. MARTEN, G. H. MORTON, W. PENGELLY, JAMES PLANT, J. PRESTWICH, I. ROBERTS, T. S. STOOKE, G. J. SYMONS, W. TOPLEY, TYLDEN-WRIGHT, E. WETHERED, W. WHITAKER, and C. E. DE RANCE (Secretary), appointed for the purpose of investigating the Circulation of Underground Waters in the Permeable Formations of England and Wales, and the Quantity and Character of the Water supplied to various Towns and Districts from these Formations. (Drawn up by C. E. DE RANCE, Reporter)	145
Report of the Committee, consisting of Mr. JOHN CORDEAUX (Secretary), Professor A. NEWTON, Mr. J. A. HARVIE-BROWN, Mr. WILLIAM EAGLE CLARKE, Mr. R. M. BARRINGTON, and Mr. A. G. MORE, reappointed at Man-	

	Page
chester for the purpose of obtaining (with the consent of the Master and Brethren of the Trinity House and the Commissioners of Northern and Irish Lights) observations on the Migration of Birds at Lighthouses and Lightvessels, and of reporting on the same.....	146
Report of the Committee, consisting of Professor W. C. WILLIAMSON and Mr. W. CASH, appointed for the purpose of investigating the Flora of the Carboniferous Rocks of Lancashire and West Yorkshire. (Drawn up by Professor W. C. WILLIAMSON)	150
Report of the Committee, consisting of Professor RAY LANKESTER, Mr. P. L. SCLATER, Professor M. FOSTER, Mr. A. SEDGWICK, Professor A. M. MARSHALL, Professor A. C. HADDON, Professor MOSELEY, and Mr. PERRY SLADEN (Secretary), appointed for the purpose of arranging for the occupation of a Table at the Zoological Station at Naples	150
Report of the Committee, consisting of Dr. J. H. GLADSTONE (Secretary), Professor ARMSTRONG, Mr. STEPHEN BOURNE, Miss LYDIA BECKER, Sir JOHN LUBBOCK, Bart., Dr. H. W. CROSSKEY, Sir RICHARD TEMPLE, Bart., Sir HENRY E. ROSCOE, Mr. JAMES HEYWOOD, and Professor N. STORY MASKELYNE, appointed for the purpose of continuing the inquiries relating to the teaching of Science in Elementary Schools	164
Sixth Report of the Committee, consisting of Mr. R. ETHERIDGE, Dr. H. WOODWARD, and Professor T. RUPERT JONES (Secretary), on the Fossil Phyllopora of the Palæozoic Rocks	173
Second Report of the Committee, consisting of Mr. S. BOURNE, Professor F. Y. EDGEWORTH (Secretary), Professor H. S. FOXWELL, Mr. ROBERT GIFFEN, Professor ALFRED MARSHALL, Mr. J. B. MARTIN, Professor J. S. NICHOLSON, Mr. R. H. INGLIS PALGRAVE, and Professor H. SIDGWICK, appointed for the purpose of investigating the best method of ascertaining and measuring Variations in the Value of the Monetary Standard. (Drawn up by Mr. GIFFEN)	181
Report of the Committee, consisting of Mr. S. BOURNE, Professor F. Y. EDGEWORTH (Secretary), Professor H. S. FOXWELL, Mr. ROBERT GIFFEN, Professor ALFRED MARSHALL, Mr. J. B. MARTIN, Professor J. S. NICHOLSON, and Mr. R. H. INGLIS PALGRAVE, appointed for the purpose of inquiring and reporting as to the Statistical Data available for determining the amount of the Precious Metals in use as Money in the principal Countries, the chief forms in which the Money is employed, and the amount annually used in the Arts. (Drawn up by the Secretary)	219
Fourth Report of the Committee, consisting of Dr. E. B. TYLOR, Dr. G. M. DAWSON, General Sir J. H. LEFROY, Dr. DANIEL WILSON, Mr. R. G. HALIBURTON, and Mr. GEORGE W. BLOXAM (Secretary), appointed for the purpose of investigating and publishing reports on the physical characters, languages, and industrial and social condition of the North-Western Tribes of the Dominion of Canada	233
Report of the Corresponding Societies Committee, consisting of Mr. FRANCIS GALTON (Chairman), Professor A. W. WILLIAMSON, Sir DOUGLAS GALTON, Professor BOYD DAWKINS, Sir RAWSON RAWSON, Dr. J. G. GARSON, Dr. J. EVANS, Mr. J. HOPKINSON, Professor R. MELDOLA (Secretary), Mr. W. WHITAKER, Mr. G. J. SYMONS, General PITT-RIVERS, Mr. W. TOPLEY, Mr. H. G. FORDHAM, and Mr. WILLIAM WHITE	255
Second Report of the Committee, consisting of Sir JOHN LUBBOCK, Dr. JOHN EVANS, Professor BOYD DAWKINS, Dr. ROBERT MUNRO, Mr. PENGELLY, Dr. HENRY HICKS, Professor MELDOLA, Dr. MUIRHAD, and Mr. JAMES W. DAVIS, appointed for the purpose of ascertaining and recording the localities in the British Islands in which evidences of the existence of Prehistoric Inhabitants of the country are found. (Drawn up by JAMES W. DAVIS) ...	289

	Page
Third Report of the Committee, consisting of Sir JOSEPH D. HOOKER, Sir JOHN HUBBOCK, Sir GEORGE NARES, General J. T. WALKER, Sir LEOPOLD MCCLINTOCK, Admiral Sir GEORGE H. RICHARDS, Professor FLOWER, Professor HUXLEY, Dr. SCLATER, Professor MOSELEY, Mr. JOHN MURRAY, General STRACHEY, Sir WILLIAM THOMSON, and Admiral Sir ERASMUS OMMANNEY (Secretary), appointed for the purpose of drawing attention to the desirability of prosecuting further research in the Antarctic Regions ...	316
Report of the Committee, consisting of Dr. ALEX. BUCHAN, Professor MCKENDRICK, Professor CHRYSTAL, and Dr. JOHN MURRAY (Secretary), appointed for the purpose of aiding in the maintenance of the establishment of a Marine Biological Station at Granton, Scotland	319
Report of the Committee, consisting of Mr. H. BAUERMAN, Mr. F. W. RUDLER, Mr. J. J. H. TEALL, and Dr. H. J. JOHNSTON-LAVIS, appointed for the investigation of the Volcanic Phenomena of Vesuvius and its neighbourhood. (Drawn up by Dr. H. J. JOHNSTON-LAVIS, M.D., F.G.S., Secretary)	320
Report of the Committee, consisting of Mr. JOHN MURRAY (Secretary), Professor CHRYSTAL, Dr. A. BUCHAN, Rev. C. J. STEWARD, the Hon. R. ABERCROMBY, Mr. J. Y. BUCHANAN, Mr. DAVID CUNNINGHAM, Mr. ISAAC ROBERTS, Dr. H. R. MILL, and Professor FITZGERALD, appointed to arrange an investigation of the Seasonal Variations of Temperature in Lakes, Rivers, and Estuaries in various parts of the United Kingdom in co-operation with the local societies represented on the Association	326
Report of the Committee, consisting of Mr. J. W. DAVIS, Mr. W. CASH, Dr. H. HICKS, Mr. G. W. LAMPLUGH, Mr. CLEMENT REID, Dr. H. WOODWARD, and Mr. T. BOYNTON, appointed for the purpose of investigating an ancient Sea-beach near Bridlington Quay. (Drawn up by G. W. LAMPLUGH, Secretary)	328
Report of the Committee, consisting of Professor LANKESTER, Professor MILNES MARSHALL, Mr. SEDGWICK, and Mr. G. H. FOWLER (Secretary), appointed for the purpose of investigating the Development of the Oviduct and connected structures in certain fresh-water Teleostei	338
Third Report of the Committee, consisting of Professors ARMSTRONG, LODGE, Sir WILLIAM THOMSON, Lord RAYLEIGH, FITZGERALD, J. J. THOMSON, SCHUSTER, POYNTING, CRUM BROWN, RAMSAY, FRANKLAND, TILDEN, HARTLEY, S. P. THOMPSON, MCLEOD, ROBERTS-AUSTEN, RÜCKER, REINOLD, CAREY FOSTER, and H. B. DIXON, Captain ABNEY, Drs. GLADSTONE, HOPKINSON, and FLEMING, and Messrs. CROOKES, SHELFORD BIDWELL, W. N. SHAW, J. LARMOR, J. T. BOTTOMLEY, R. T. GLAZEBROOK, J. BROWN, E. J. LOVE, and JOHN M. THOMSON, appointed for the purpose of considering the subject of Electrolysis in its Physical and Chemical Bearings	339
Report of the Committee, consisting of Messrs. W. CARRUTHERS, W. F. R. WELDON, J. G. BAKER, G. M. MURRAY, and W. T. THISELTON-DYER (Secretary), appointed for the purpose of exploring the Flora of the Bahamas.....	361
Second Report of the Committee, consisting of Professors SCHÄFFER (Secretary), MICHAEL FOSTER, and LANKESTER and Dr. W. D. HALLIBURTON, appointed for the purpose of investigating the Physiology of the Lymphatic System. (Drawn up by Dr. W. D. HALLIBURTON)	363
Report of the Committee, consisting of Professor T. G. BONNEY, Mr. J. J. H. TEALL, and Professor J. F. BLAKE (Secretary), appointed to investigate the Microscopic Structure of the Older Rocks of Anglesey. (Drawn up by the Secretary)	367
Report of the Committee, consisting of Mr. THISELTON-DYER (Secretary), Mr. CARRUTHERS, Mr. BALL, Professor OLIVER, and Mr. FORBES, appointed for the purpose of continuing the preparation of a Report on our present knowledge of the Flora of China	420
Second Report of the Committee, consisting of Professor FOSTER, Professor	

	Page
BAYLEY BALFOUR, Mr. THISSELTON-DYER, Dr. TRIMEN, Professor MARSHALL, WARD, Mr. CARRUTHERS, Professor HARTOG, and Professor BOWER (Secretary), appointed for the purpose of taking steps for the establishment of a Botanical Station at Peradeniya, Ceylon.....	421
Eighth Report of the Committee, consisting of Mr. R. ETHERIDGE, Mr. THOMAS GRAY, and Professor JOHN MILNE (Secretary), appointed for the purpose of investigating the Earthquake and Volcanic Phenomena of Japan. (Drawn up by the Secretary)	422
Report of the Committee, consisting of Mr. THISSELTON-DYER (Secretary), Professor NEWTON, Professor FLOWER, Mr. CARRUTHERS, and Mr. SCLATER, appointed for the purpose of reporting on the present state of our knowledge of the Zoology and Botany of the West India Islands, and taking steps to investigate ascertained deficiencies in the Fauna and Flora	437
Second Report on our Experimental Knowledge of the Properties of Matter with respect to Volume, Pressure, Temperature, and Specific Heat. By P. T. MAIN, M.A.	465
Report of the Committee, consisting of Sir F. J. BRAMWELL, Mr. E. A. COWPER, Mr. G. J. SYMONS, Professors G. H. DARWIN and EWING, Mr. ISAAC ROBERTS, Mr. THOMAS GRAY, Dr. JOHN EVANS, Professors LEBOUR, PRESTWICH, HULL, MELDOLA, and JUDD, and Mr. J. GLAISHER, appointed for the purpose of considering the advisability and possibility of establishing in other parts of the country observations upon the prevalence of Earth Tremors similar to those now being made in Durham	522
The Relations between Sliding Scales and Economic Theory. By L. L. PRICE, M.A.	523
Index-numbers as illustrating the Progressive Exports of British Produce and Manufactures. By STEPHEN BOURNE, F.S.S.	536
The Friction of Metal Coils. By Professor HELE SHAW and EDWARD SHAW	540
Sur l'application de l'analyse spectrale à la mécanique moléculaire et sur les spectres de l'oxygène. Par Dr. J. JANSSEN	547

TRANSACTIONS OF THE SECTIONS.

SECTION A.--MATHEMATICAL AND PHYSICAL SCIENCE.

THURSDAY, SEPTEMBER 6.

	Page
Address by Professor G. F. FITZGERALD, M.A., F.R.S., President of the Section.....	557
1. Fourth Report of the Committee for promoting Tidal Observations in Canada	562
2. On the Behaviour of Water under great Provocation from Heat. By Professor W. RAMSAY, F.R.S.	562
3. On the Proof of the Logarithmic Law of Atomic Weights. By Dr. G. JOHNSTONE STONEY, F.R.S.	562
4. On the Oscillations of a Rotating Liquid Spheroid and the Genesis of the Moon. By A. E. H. LOVE, B.A.	562
5. Waves in a Viscous Liquid. By A. B. BASSET, M.A.	563
6. On a Hydrostatic Balance. By J. JOLY, M.A., B.E.....	564
7. On the Meldometer. By J. JOLY, M.A., B.E.....	564
8. Electro-calorimetry. By Professor WILLIAM STROUD, B.A., D.Sc., and W. W. HALDANE GEE, B.Sc.	565
9. On Figures produced by Electric Action on Photographic Dry Plates. By J. BROWN.	565
10. Comparison of Gassner's Dry Cells with Leclanché's. By WM. LANT CARPENTER.....	566
11. On the Intensity of Magnetisation of soft Iron Bars of various lengths in a uniform Magnetic Field. By A. TANAKADATÉ.	566

FRIDAY, SEPTEMBER 7.

1. Recent Progress in the Use of Concave Gratings for Spectrum Analysis. By Professor H. A. ROWLAND	566
2. Is the Velocity of Light in an Electrolytic Liquid influenced by an Electric Current in the direction of propagation? By Lord RAYLEIGH, LL.D., Sec. R.S.....	566
3. On the Measurement of the Length of Electro-magnetic Waves. By Professor OLIVER J. LODGE, F.R.S.....	567
4. On the Impedance of Conductors to Leyden-jar Discharges. By Professor OLIVER J. LODGE, F.R.S.	567

CONTENTS.

	Page
5. A simple hypothesis for Electro-magnetic Induction of incomplete circuits, with consequent equations of Electric Motion in fixed homogeneous or heterogeneous solid matter. By Professor Sir WILLIAM THOMSON, LL.D., F.R.S.	567
6. On the Transference of Electricity within a Homogeneous Solid Conductor. By Professor Sir WILLIAM THOMSON, LL.D., F.R.S.	570
7. Five Applications of Fourier's Law of Diffusion, illustrated by a Diagram of Curves with Absolute Numerical Values. By Professor Sir WILLIAM THOMSON, LL.D., F.R.S.	571
8. On Flux and Reflux of Water in Open Channels or in Pipes or other Ducts. By Professor JAMES THOMSON, LL.D., F.R.S.	574

SATURDAY, SEPTEMBER 8.

DEPARTMENT FOR LIGHT AND ELECTRICITY.

1. Sur l'application de l'analyse spectrale à la mécanique moléculaire et sur les spectres de l'oxygène. By Dr. J. JANSSEN	576
2. On the Absorption Spectrum of Oxygen. By Professors LIVEING, F.R.S., and DEWAR, F.R.S.....	576
3. The Spectra of Meteorites compared with the Solar Spectrum. By J. NORMAN LOCKYER, F.R.S.	576
4. On the Harmonic Series of Lines in the Spectra of the Elements. By Professor CARL RUNGE	576
5. A Vortex Analogue of Static Electricity. By Professor W. M. HICKS, M.A., F.R.S.	577
6. On a Diffusion Photometer. By J. JOLY, M.A., B.E.	578
7. Third Report of the Committee on Electrolysis.....	578

DEPARTMENT FOR MATHEMATICS AND GENERAL PHYSICS.

1. On Centres of Finite Twist and Stretch. By Professor R. W. GENESE, M.A.	579
2. On Recurring Decimals and Fermat's Theorem. By Professor R. W. GENESE, M.A.	580
3. On the Relations between Orbits, Catenaries, and Curved Rays. By Professor J. D. EVERETT, F.R.S.	581
4. On the Stretching of Liquids. By Professor A. M. WORTHINGTON, M.A., F.R.S.	583
5. A new Sphere Planimeter. By Professor HELL SHAW, M.Inst.C.E.	584
6. On Composition of Sensation and Notion of Space. By L. DE LA RIVE...	585

MONDAY, SEPTEMBER 10.

1. Third Report of the Committee for inviting Designs for a good Differential Gravity Meter.....	586
2. Fourth Report of the Committee for considering the best means of Comparing and Reducing Magnetic Observations.	586
3. Third Report of the Committee appointed to co-operate with the Scottish Meteorological Society in making Meteorological Observations on Ben Nevis	586

	Page
4. Modern Views about Hurricanes, as compared with the Older Theories. By Hon. RALPH ABERCROMBY, F.R.Met.Soc.	586
5. Report of the Committee appointed to arrange an investigation of the Seasonal Variations of Temperature in Lakes, Rivers, and Estuaries in various parts of the United Kingdom.....	587
6. On the Temperature of some Scottish Rivers. By HUGH ROBERT MILL, D.Sc., F.R.S.E.	588
7. On the recent Magnetic Survey of Japan. By Professor CARGILL G. KNOTT, D.Sc., F.R.S.E.	588
8. On Reading Electrically Meteorological Instruments distant from the Observer. By J. JOLY, M.A., B.E.....	589
9. On the Mechanical Conditions of a Swarm of Meteorites, and on Theories of Cosmogony. By Professor G. H. DARWIN, F.R.S.	590
10. On some accurate Charts of Kew Corrections for Mercury Thermometers. By W. N. SHAW, M.A.	590
11. On an Apparatus for determining Temperature by the Variation of Electrical Resistance. By W. N. SHAW, M.A.....	590
12. Fourth Report of the Committee on Standards of Light.	591

TUESDAY, SEPTEMBER 11.

1. Joint Discussion with Section G on Lightning-conductors	591
2. On the Burning by Lightning of a Magnet on a Generating Dynamo at the Waterfall on the Bush River, County Antrim, belonging to the Giant's Causeway and Portrush Electric Railway and Tramway Com- pany. By ANTHONY TRAILL, LL.D., M.D.	615
3. Analyse chronométrique des Phénomènes électriques lumineux. Par Dr. J. JANSSEN	615
4. Report of the Committee for constructing and issuing Practical Standards for use in Electrical Measurements	616
5. On Standards of Electrical Resistance. By R. T. GLAZEBROOK, F.R.S. ...	616
6. On the C.G.S. Units of Measurement. By W. H. PREECE, F.R.S.	616
7. Electrometric Determination of 'v.' By Professors Sir W. THOMSON, F.R.S., AYRTON, F.R.S., and PERRY, F.R.S.	616

WEDNESDAY, SEPTEMBER 12.

1. Report of the Committee for considering the desirability of introducing a Uniform Nomenclature for the Fundamental Units of Mechanics	616
2. Second Report on our Experimental Knowledge of the Properties of Matter. By P. T. MAIN, M.A.	616
3. On the Mechanical Arrangements of the Analytical Engine of the late Charles Babbage, F.R.S. By Major-General H. P. BABBAGE.....	616
4. On a Modification of Maxwell's Equations of Electromagnetic Waves. By Professor H. A. ROWLAND	617
5. On a Photographic Image of an Electric Arc Lamp, probably due to Phosphorescence in the Eye, and on some Photographs of an Eclipse of the Moon. By FRIESE GREENE	617
6. On the Errors of the Argument of Statistical Tables. By JOSEPH KLEIBER	618

	Page
7. On Geometry of Four Dimensions. By EDWARD T. DIXON	618
8. A Suggestion from the Bologna Academy of Science towards an agreement on the Initial Meridian for the Universal Hour. By Dr. CÆS. TONDINI DE QUARENGHI	618

SECTION B.—CHEMICAL SCIENCE.

THURSDAY, SEPTEMBER 6.

Address by Professor W. A. TILDEN, D.Sc., F.R.S., F.C.S., President of the Section.....	620
1. Report of the Committee for the investigation of the action of Light on the Hydracids of Halogens in presence of Oxygen	627
2. Second Report of the Committee on the Bibliography of Solution	627
3. Second Report of the Committee for investigating the Nature of Solution	627
4. Second Report of the Committee for investigating the Influence of Silicon on the properties of Steel	627
5. On the Study of Mineralogy. By T. STERRY HUNT, LL.D., F.R.S.	627
6. On the Logarithmic Law and its connection with the Atomic Weights. By Dr. G. JOHNSTONE STONEY, F.R.S.....	630
7. On Dissociation. By the Rev. A. IRVING, D.Sc., B.A.....	630
8. On Closed-chain Formulæ. By J. E. MARSH, B.A.	631
9. On Van't Hoff's Hypothesis and the Constitution of Benzene. By J. E. MARSH, B.A.	631

FRIDAY, SEPTEMBER 7.

1. Discussion on the Chemical Problems presented by Living Bodies, opened by Professor MICHAEL FOSTER, Sec.R.S.....	631
2. On the Atomic Weight of Oxygen. By ALEXANDER SCOTT, M.A., D.Sc., F.R.S.E.	631
3. The Incompleteness of Combustion in Explosions. By Professor H. B. DIXON, F.R.S., and H. W. SMITH, B.Sc.	632
4. A new Gas Analysis Apparatus. By W. W. J. NICOL, M.A., D.Sc.	632
5. The Determination of Vapour-densities at High Temperatures and under Reduced Pressure. By Dr. WILLIAM BOTT, F.C.S.	632
6. On Photographing Hydrogen and Chlorine Bulbs by aid of the Flash of Light which caused their Explosion. By Professor P. PHILLIPS BEDSON, D.Sc.	633
7. On the Formation of Crystals of Calcium Oxide and Magnesium Oxide in the Oxyhydrogen Flame. By J. JOLY, M.A., B.E.	634

SATURDAY, SEPTEMBER 8.

1. Report of the Committee on the present methods of teaching Chemistry...	634
2. Chemistry as a School Subject. By the Rev. A. IRVING, D.Sc., B.A. ...	634

MONDAY, SEPTEMBER 10.

1. Discussion on Valency, opened by Professor H. E. ARMSTRONG, F.R.S. ...	635
2. Evidence of the Tetravalency of Oxygen derived from the Constitution of the Azonaphthol-Compounds. By Professor R. MELDOLA, F.R.S., F.C.S., F.I.C.	635

3. The Theory of Solution. By T. STERRY HUNT, LL.D., F.R.S. 636
4. The Composition of, Copper-Tin Alloys. By A. P. LAURIE..... 637
5. The Composition of the ancient Roman Mortar from the London Wall.
By JOHN SPILLER, F.C.S. 637
6. On the Rate of Solution of Copper in Acids. By V. H. VELBY, M.A. ... 638
7. Recovery of the Ammonia and Chlorine in the Ammonia-soda Process.
By F. BALE 638

TUESDAY, SEPTEMBER 11.

1. Third Report of the Committee for investigating Isomeric Naphthalene
Derivatives 640
2. Note on the Molecular Weight of Caoutchouc and other Colloids. By Dr.
J. H. GLADSTONE, F.R.S., and W. HIBBERT, F.I.C. 640
3. On some new Silicon Compounds. By Professor J. EMERSON REYNOLDS,
M.D., F.R.S. 640
4. On some new Thiocarbamide Compounds. By Professor J. EMERSON
REYNOLDS, M.D., F.R.S. 640
5. Proposed International Standards to control the Analysis of Iron and
Steel. By Professor J. W. LANGLEY 640
6. On the Action of Light on Water Colours. By ARTHUR RICHARD-
SON, Ph.D. 641
7. Further Researches on the Pyrocresols. By Dr. WILLIAM BOTT, F.C.S.,
and J. BRUCE MILLER, F.I.C. 642

SECTION C.—GEOLOGY.

THURSDAY, SEPTEMBER 6.

- Address by Professor W. BOYD DAWKINS, M.A., F.R.S., F.G.S., F.S.A.,
President of the Section..... 644
1. Further Note on the Midford Sands. By HORACE B. WOODWARD, F.G.S. 650
 2. The Relations of the Great Oolite to the Forest Marble and Fuller's-earth
in the South-west of England. By HORACE B. WOODWARD, F.G.S. 651
 3. Note on the Portland Sands of Swindon and elsewhere. By HORACE B.
WOODWARD, F.G.S. 652
 4. On Local Geological Photography. By OSMUND W. JEFFS..... 653
 5. Further Notes on the Origin of the Crystalline Schists of Malvern and
Anglesey. By CHARLES CALLAWAY, D.Sc., M.A., F.G.S. 653
 6. Sketch of the Geology of the Crystalline Axis of the Malvern Hills. By
CHARLES CALLAWAY, D.Sc., M.A., F.G.S. 654
 7. Archean Characters of the Rocks of the Nucleal Ranges of the Antilles.
By Dr. PERSIFOR FRAZER..... 654
 8. On a Specimen of Quartz from Australia and Three Specimens of Oligo-
clase from North Carolina exhibiting curious Optical Properties. By
Dr. PERSIFOR FRAZER 655

FRIDAY, SEPTEMBER 7.

1. Sixteenth Report on the Erratic Blocks of England, Wales, and Ireland... 656
2. On a High Level Boulder-clay in the Midlands. By Dr. H. W. CROSS-
KEY, F.G.S. 656

	Page
3. On the Extension of the Bath Oolite under London, as shown by a Deep Boring at Streatham. By W. WHITAKER, B.A., F.R.S.....	656
4. On the Lower Carboniferous Rocks of Gloucestershire. By E. WETHERED, F.G.S., F.C.S., F.R.M.S.	657
5. On the Tytherington and Thornbury Section. By the Rev. H. H. WINWOOD, F.G.S.	658
6. The Northern Section of the Bristol Coal-field. By HANDEL COSSHAM, M.P., F.G.S.	659
7. Some Points of Interest in the Geology of Somerset. By W. A. E. USSHER, F.G.S.	659

SATURDAY, SEPTEMBER 8.

1. Comparison of the principal Forms of Dinosauria of Europe and America. By Professor O. C. MARSH	660
2. The Evolution of the Mammalian Molar Teeth to and from the Tritubercular Type. By HENRY FAIRFIELD OSBORN	660
3. On the Gigantic Size of some extinct Tertiary Mammalia. By Professor A. GAUDRY	660
4. Note on the Relation of the Percentage of Carbonic Acid in the Atmosphere to the Life and Growth of Plants. By the Rev. A. IRVING, D.Sc., B.A., F.G.S.	661
5. On the Occurrence of a Boulder of Granitoid Gneiss or Gneissoid Granite in the Halifax Hard-bed Coal. By JAMES SPENCER. With a Note by Professor T. G. BONNEY.....	661
6. The Caverns of Luray. By the Chevalier R. E. REYNOLDS	662
7. Report on the Rate of Erosion of the Sea-coasts of England and Wales ...	663

MONDAY, SEPTEMBER 10.

1. The Volcanoes of the Two Sicilies. By TEMPEST ANDERSON, M.D., B.Sc.	663
2. Notes on the late Eruption in the island of Vulcano. By TEMPEST ANDERSON, M.D., B.Sc., and H. J. JOHNSTON-LAVIS, M.D., F.G.S.	664
3. Report on the Volcanic Phenomena of Vesuvius and its neighbourhood ...	666
4. On the Conservation of Heat in Volcanic Chimneys. By H. J. JOHNSTON-LAVIS, M.D., F.G.S.	666
5. Note on a Mass containing Metallic Iron found on Vesuvius. By H. J. JOHNSTON-LAVIS, M.D., F.G.S.....	667
6. Note on the Occurrence of Leucite at Etna. By H. J. JOHNSTON-LAVIS, M.D., F.G.S.	669
7. Note on some recent Investigations into the Condition of the Interior of the Earth. By Professor E. W. CLAYPOLE, B.A., D.Sc., F.G.S.	669
8. On the Causes of Volcanic Action. By J. LOGAN LOBLEY, F.G.S.	670
9. Eighth Report on the Earthquake and Volcanic Phenomena of Japan.....	671
10. On the recent Volcanic Structure of the Azorean Archipelago. By OSBERT H. HOWARTH.....	671
11. Report of the Earth Tremor Committee	671

SUB-SECTION C.

	Page
1. The Watcombe Terra-Cotta Clay. By W. A. E. USSHER, F.G.S.	672
2. Second Report on the 'Manure' Gravels of Wexford	672
3. Beds exposed in the Southampton New Dock Excavation. By T. W. SHORE, F.G.S., F.C.S.	672
• 4. Fossil Arctic Plants from the Lacustrine Deposit at Hoxne, in Suffolk. By CLEMENT REID, F.G.S., and H. N. RIDLEY, M.A., F.L.S.	674
5. Report on an ancient Sea Beach near Bridlington Quay	674
6. On the Origin of Oolitic Texture in Limestone Rocks. By Professor H. G. SEELEY, F.R.S.	674

TUESDAY, SEPTEMBER 11.

1. Notes of some Researches on the Fossil Fishes of Chiavòn, Vicentino (Stratum of Sotzka, Lower Miocene). By Professor FRANCESCO BASSANI	675
2. Sixth Report on the Fossil Phyllopoda of the Palæozoic Rocks	677
3. Report of the Committee for investigating the Flora of the Carboniferous Rocks of Lancashire and West Yorkshire	677
4. On an <i>Ichthyosaurus</i> from Mombasa, East Africa, with Observations on the Vertebral Characters of the Genus. By Professor H. G. SEELEY, F.R.S.	677
5. A Comparison of the Cretaceous Fish-fauna of Mount Lebanon with that of the English Chalk. By A. SMITH WOODWARD, F.G.S., F.Z.S.	678
6. On <i>Bucklandium diluvii</i> , König, a Siluroid Fish from the London Clay of Sheppey. By A. SMITH WOODWARD, F.G.S., F.Z.S.	679
7. On the Origin of Graphite in the Archæan Rocks, with a Review of the alleged Evidence of Life on the Earth in Archæan Time. By the Rev. A. IRVING, D.Sc., B.A., F.G.S.	679
8. On some Devonian Cephalopods and Gasteropods. By the Rev. G. F. WHIDBORNE, M.A., F.G.S.	680
9. On some Devonian Crustaceans. By the Rev. G. F. WHIDBORNE, M.A., F.G.S.	681
10. On some Fossils of the Limestones of South Devon. By the Rev. G. F. WHIDBORNE, M.A., F.G.S.	681

SUB-SECTION C.

1. Mineralogical Evolution. By T. STERRY HUNT, LL.D., F.R.S.	682
2. Report on the Microscopic Structure of the Older Rocks of Anglesey.....	684
• 3. On a probable Cause of Contortions of Strata. By CHARLES RICKETTS, M.D., F.G.S.	684
• 4. On the Temperature at which Beryl is decolorised. By J. JOLY, M.A., B.E.	684
5. On the Occurrence of Iolite in the Granite of County Dublin. By J. JOLY, M.A., B.E.	685
6. An Igneous Succession in Shropshire. By W. W. WATTS, M.A., F.G.S.	685
7. Fourteenth Report on the Circulation of Underground Waters.....	685
8. A List of Works referring to British Mineral and Thermal Waters. By H. DALTON.	685

SECTION D.—BIOLOGY.

THURSDAY, SEPTEMBER 6.

	Page
Address by W. T. THEISELTON-DYER, C.M.G., M.A., B.Sc., F.R.S., F.L.S., President of the Section.....	686
1. Report of the Committee for exploring the Flora of the Bahamas	701
2. Second Report of the Committee for taking steps for the establishment of a Botanical Station at Peradeniya, Ceylon.....	701
3. Report of the Committee for continuing the preparation of a Report on our present knowledge of the Flora of China	701
4. A Lily Disease. By Professor H. MARSHALL WARD, F.R.S.	702
5. On the Morphology of the Pitcher of <i>Nepenthes</i> . By Professor BOWER, F.L.S.	702
6. On <i>Adelphotaxy</i> : an undescribed Form of Irritability. By Professor MARCUS M. HARTOG, D.Sc., M.A.....	702

ZOOLOGICAL DEPARTMENT.

1. Report of the Committee for reporting on the present state of our know- ledge of the Zoology and Botany of the West India Islands, and taking steps to investigate ascertained deficiencies in the Fauna and Flora	702
2. Report of the Committee to arrange for the occupation of a Table at the Zoological Station at Naples	703
3. Report of the Committee for making arrangements for assisting the Marine Biological Association Laboratory at Plymouth.....	703
4. Report of the Committee for continuing the Researches on Food-Fishes at the St. Andrews Marine Laboratory	703
5. Report of the Committee on the Migration of Birds	703
6. On the Irruption of <i>Syrrhaptes paradoxus</i> . By Professor NEWTON, M.A., F.R.S.	703
7. Remarks on some Teleostean Ova, and their Development. By J. T. CUNNINGHAM, B.A., F.R.S.E.	703

FRIDAY, SEPTEMBER 7.

PHYSIOLOGICAL DEPARTMENT.

1. On the Physiological Bearing of Waist-belts and Stays. By Professor ROY, M.D., F.R.S., and J. G. ADAMI, M.A.	704
---	-----

ZOOLOGICAL DEPARTMENT.

1. Some Remarks on the Instincts of Solitary Wasps and Bees. By Sir JOHN LUSBOCK, Bart., F.R.S.	706
2. Restoration of <i>Brontops Robustus</i> , from the Miocene of America. By Professor O. C. MARSH, Ph.D., LL.D.	706
3. Heredity in Cats with an extra Number of Toes. By E. B. POUETON, M.A.	707
4. On the Nature of the Geological Terrain as an important factor in the Geographical Distribution of Animals. By HANS GADOW, M.A., Ph.D....	707
5. On the Natural History of Christmas Island. By J. J. LISTER, M.A., F.Z.S.	708

MONDAY, SEPTEMBER 10.

	Page
1. Report of the Committee for aiding in the maintenance of the establishment of a Marine Biological Station at Granton, Scotland	710
2. Report of the Committee on the Development of the Oviduct in certain fresh-water Teleostei	710
• 3. On certain Adaptations for the Nutrition of Embryos. By F. W. OLIVER.....	710
• 4. On the Development of the Bulb in <i>Laminaria bulbosa</i> . By C. A. BARBER	710
5. On <i>Pachythea</i> , a Silurian Alga of doubtful Affinities. By C. A. BARBER	711
6. On the Plant-remains discovered by Mr. W. M. Flinders Petrie in the Cemetery of Hawara, Lower Egypt. By PERCY E. NEWBERRY.....	712
7. Abnormal Ferns, Hybrids, and their Parents. By E. J. LOWE, F.R.S., and Colonel JONES	713
8. Preliminary Note on the Functions and Homologies of the Contractile Vacuole in Plants and Animals. By Professor MARCUS M. HARTOG, D.Sc., M.A.	714
• 9. On the Contrivances for the Seed Protection and Distribution in <i>Blumenbachia Hieronymi</i> , Urban. By W. GARDINER	716

ZOOLOGICAL DEPARTMENT.

1. On Locusts in Cyprus. By S. BROWN	716
2. On the Fauna of the Firth of Clyde. By W. E. HOYLE, M.A.	717
3. On a Deep-sea Tow Net. By W. E. HOYLE, M.A.	717
4. On some Points in the Natural History of the Coral <i>Fungia</i> . By J. J. LISTER, M.A., F.Z.S.	717
5. On the Echinodermata of the Sea of Bengal. By Professor F. JEFFREY BELL, M.A., Sec. R.M.S.	718

TUESDAY, SEPTEMBER 11.

1. Discussion on Coral Reefs	718
2. Second Report of the Committee on the Physiology of the Lymphatic System.....	723
3. Contributions to the Anatomy of the Tubificidæ. By F. E. BEDDARD, M.A., F.Z.S.	723
4. On the Flora of Madagascar. By the Rev. R. BARON	724
5. On the Effects of the Weather of 1888 on the Animal and Vegetable Kingdoms. By E. J. LOWE, F.R.S.	726
6. The Odoriferous Apparatus of the <i>Blaps mortisaga</i> (Coleoptera). By Professor GUSTAVE GILSON	727
7. Report of the Committee on Provincial Museums	728
8. The effect of various substances (chiefly members of the aromatic series of organic compounds) upon the rate of secretion and constitution of the Bile. By W. J. COLLINS, M.D., M.S., B.Sc. (Lond.), F.R.C.S.	728

1888.

SECTION E.—GEOGRAPHY.

THURSDAY, SEPTEMBER 6.

	Page
Address by Colonel Sir O. W. WILSON, R.E., K.C.B., K.C.M.G., D.C.L., F.R.S., F.R.G.S., President of the Section	729
1. Le Canal de Panama. Par F. DE LESSEPS	738
2. Meteorological Conditions of the Red Sea. By Lieut.-General STRACHEY, F.R.S.	738
3. Sea Temperatures in the neighbourhood of Cape Guardafui. By Lieut.- General STRACHEY, F.R.S.,	738
4. The Salinity of the Clyde Sea Area. By HUGH ROBERT MILL, D.Sc., F.R.S.E.	738
5. Sea Temperatures on the Continental Shelf. • By HUGH ROBERT MILL, D.Sc., F.R.S.E.	739
6. Perspective Maps and Common Maps. By ARTHUR W. CLAYDEN, M.A., F.G.S.	740
7. 'Little Russia.' By E. DELMAR MORGAN, F.R.G.S.	740
8. Third Report of the Committee appointed for the purpose of drawing attention to the desirability of prosecuting further research in the Ant- arctic Regions.....	745

FRIDAY, SEPTEMBER 7.

1. Explorations on the Chindwin River, Upper Burmah, in 1886-87. By Colonel WOODTHORPE, R.E.	741
2. A new Route from India to Tibet. By Captain W. J. ELWES	741
3. Russian Topographical Surveys. By E. DELMAR MORGAN, F.R.G.S.....	741
4. Notes on the Geography of the Region from the Nile to the Euphrates as known to the ancient Egyptians. By the Rev. HENRY GEORGE TOMKINS	741
5. Remarks on Mr. Tomkins's Paper. By Major CONDER, R.E.	743
6. Recent Explorations East of the Jordan. By Captain A. M. MANTELL, R.E.....	743
7. Jerusalem: Nehemiah's Wall and the Royal Sepulchres. By GEORGE St. CLAIR, F.G.S.	744

MONDAY, SEPTEMBER 10.

1. Tunis since the French Protectorate. By Colonel Sir LAMBERT PLAYFAIR, K.C.M.G.....	745
2. The Commercial Future of Central Africa. By Colonel Sir FRANCIS DE WINTON	745
3. Bechuanaland and the Land of Ophir. By the Rev. JOHN MACKENZIE ...	745
4. The Transvaal, or South African Republic. By P. H. FORD	745
5. The Cameroons. By H. H. JOHNSTON	745
6. Dr. Livingstone and Lake Bangweolo. By E. G. RAVENSTEIN	745
7. Notes from the Atlas Mountains. By Jos. THOMSON	745
8. Akkas and Dwarfs in Southern Morocco. By R. G. HALIBURTON	745
9. Through Kakongo. By Q. E. DENNETT	745

TUESDAY, SEPTEMBER 11.

	Page
1. Photographic and Photozincographic Processes employed in the Ordnance Survey. By Colonel J. H. BOLLAND, R.E.	746
2. Note on Geographical Terminology. By H. J. MACKINDER, M.A.	746
3. The River of Joseph, the Fayum and Raian Basins. By COPE WHITEHOUSE, M.A.	746
4. Mission to El-Wedj. By Captain CONYERS SURTEES	747
5. Notes on Topographic Maps produced by the United States Geological Survey. By G. K. GILBERT.	747
6. Pahang, an Independent State in the Malayan Peninsula. By W. BARRINGTON D'ALMEIDA	747
7. Formosa: Characteristic Traits of the Island and its Aboriginal Inhabitants. By GEORGE TAYLOR	747
8. On the general adoption of the Gregorian Calendar in relation with that of the universal hour. By Dr. CÆS. TONDINI DE QUARENGHI	747

SECTION F.—ECONOMIC SCIENCE AND STATISTICS.

THURSDAY, SEPTEMBER 6.

Address by The Right Hon. Lord BRAMWELL, LL.D., F.R.S., F.S.S., President of the Section.	749
1. On Mining Royalties and their effect on the Iron and Coal Industries. By Professor W. R. SORLEY.	755
2. The Relations between Sliding Scales and Economic Theory. By L. L. PRICE, M.A.	757
3. On Wage Statistics and Theories. By JAMES MAVOR	757
4. The Growth of American Industries and Wealth. By MICHAEL GEORGE MULHALL, F.S.S.	757
5. Somersetshire Cider. By JOHN HIGGINS	759
6. Agricultural, Commercial, Industrial, and Banking Statistics. By WM. BOTLY, M.R.A.S.E.	760

FRIDAY, SEPTEMBER 7.

1. An Analysis of the Current Conception of State Socialism. By Professor HENRY SIDGWICK, M.A.	760
2. The Transition to Social Democracy. By G. BERNARD SHAW.	761
3. The Tendency of Competition to result in Monopoly. By Professor FOXWELL	762
4. Associative Economics applied to Colonisation. By W. L. REES	762
5. On the Statistics of Examination. By Professor F. Y. EDGEWORTH, M.A., F.S.S.	763

SATURDAY, SEPTEMBER 8.

1. The Revenue System of the United States. By ALBERT SHAW, Ph.D. ...	763
2. On the Distribution of the Licences proposed to be transferred in aid of Local Expenditure. By R. H. INGLIS PALGRAVE, F.R.S., F.S.S.	764

	Page
3. The Standard, or Basis, of Taxation. By CLAIR J. GRECE, LL.D.....	765
4. The Suitability of Small Towns for Factory Industries. By RUSSELL R. TANNER	767

MONDAY, SEPTEMBER 10.

1. Second Report of the Committee on the method of ascertaining and measuring Variations in the Value of the Monetary Standard	767
2. Index-numbers as illustrating the Progressive Exports of British Produce and Manufactures. By STEPHEN BOURNE, F.S.S.....	767
3. Report of the Committee on the Statistical Data available for determining the amount of the Precious Metals in use as Money in the principal Countries, the chief forms in which the Money is employed, and the amount annually used in the Arts	767
4. An Examination into the Reasons of the Price of Wheat rising or falling contemporaneously with the Variation in the Value of Foreign Currencies. By W. J. HARRIS, F.S.S.	767
5. The Effects on Indian Exports of the Fall in the Gold Price of Silver. By L. O. PROBYN	768
6. On Statigrams, with some suggestions for Greater Uniformity in Comparative Graphics. By the Rev. J. F. HEYES, M.A., F.C.S., F.R.G.S. ...	769
7. Reasons for a Quinquennial Census. By G. B. LONGSTAFF, M.A., M.B., F.R.C.P.	769

TUESDAY, SEPTEMBER 11.

1. Leasehold Enfranchisement. By CHARLES HARRISON	770
2. Report of the Committee for continuing the inquiries relating to the teaching of Science in Elementary Schools	771
3. The Industrial Education of Women abroad and at home. By E. J. WATHERSTON	771
4. Irishwomen's Industries. By Miss HELEN BLACKBURN	772
5. Education: a Chapter of Economics. By T. W. DUNN, M.A.	773
6. L'organisation et la statistique de l'enseignement technique secondaire en Italie. By Signor BONGHI	774
7. Agricultural Education. By Professor JAMES LONG	776
8. Economy in Education and in Writing. By EIZAK PITMAN	776

WEDNESDAY, SEPTEMBER 12.

1. The Malthusian Theory. By EDWIN CHADWICK, C.B.	777
2. Dairy Industry. By GEORGE GIBBONS	778
3. Amendments founded on Experiences submitted for the Local Government Bill. By EDWIN CHADWICK, C.B.	779
4. The Vital and Commercial Statistics of Bath. By F. NORFOLK	780
5. Old Age and Sickness Assurance for the Mercantile and Professional Classes. By F. NORFOLK	780

SECTION G.—MECHANICAL SCIENCE.

THURSDAY, SEPTEMBER 6.

	Page
Address by W. H. PREECE, F.R.S., M.Inst.C.E., President of the Section.....	781
1. The Phonograph. By Colonel G. E. GOUBAUD	792
2. The Graphophone. By HENRY EDMUNDS	792
3. Mechanical Pathology considered in its relation to Bridge Design. By • G. H. THOMSON, M.Am.S.E.....	793
4. A few Arguments in favour of Light or Road Railways. By THOS. STEPHEN P. W. D'ALTE SELLON, Assoc.M.Inst.C.E.....	794

FRIDAY, SEPTEMBER 7.

1. The Barry Docks. By JOHN WOLFE BARRY, M.Inst.C.E.	795
2. Plant and Machinery in use on the Manchester Ship Canal. By LIONEL B. WELLS, M.Inst.C.E.	796
3. On an improved Canal Lift. By S. LLOYD.....	797
4. On the Replenishment of the Underground Waters of the Permeable • Formations of England. By J. BAILEY DENTON, M.Inst.C.E., F.G.S. ...	797
5. The Raiyān Project for the Storage of Nile Flood. By COPE WHITE- HOUSE, M.A.	799
6. The Severn Watershed. By J. W. WILLIS BUND	799

SATURDAY, SEPTEMBER 8.

1. On Rolling Seamless Tubes from Solid Bars or Ingots, by the Mannesmann Process. By FREDERICK SIEMENS	804
2. Gaseous Fuel. By J. EMERSON DOWSON, M.Inst.C.E.	805
3. The Shipman Engine. By W. R. PIDGEON, M.A.....	806
4. On the Disengaging of Boats, &c. By E. J. HILL.....	807
5. The old Orkney Click Mill. By Professor A. JAMIESON, M.Inst.C.E.....	807

MONDAY, SEPTEMBER 10.

1. On the application of Electricity to the working of a 20-ton Travelling Crane. By W. ANDERSON, M.Inst.C.E.	808
2. On recent Developments of the Cowles Aluminium Process. By R. E. CROMPTON	809
3. Electric Lighting in America. By Professor GEORGE FORBES, F.R.S. ...	813
4. On a System of Electrical Distribution. By HENRY EDMUNDS	813
5. The Measurement of Electricity in a House to House Supply. By W. LOWRIE	814
6. Electric Light applied to Night Navigation upon the Suez Canal. By R. PERCY SELLON	814
7. Electricity as applied to Mining. By FRANK BRAIN	815
8. Miners' Electric Safety Lamps. By NICHOLAS WATTS, Assoc.M.Inst.C.E.	816
9. On an Automatic Fire-damp Detector. By JOSEPH WILSON SWAN, M.A.	817

TUESDAY, SEPTEMBER 11.

	Page
1. An improved Seismograph. By E. A. COWPER, M.Inst.C.E.	818
2. The Friction of Metal Coils. By Professor H. S. HELE SHAW and E. SHAW	819
3. Steam Engine Diagrams. By M. F. FITZGERALD	819
4. The Efficiency of Steam at High Pressures and the Carnot Theorem. By W. WORBY BEAUMONT, M.Inst.C.E.	820
5. Revolving Sails, or Air-propellers. By H. C. VOGT	820
6. A new Sphere Planimeter. By Professor H. S. HELE SHAW	821

WEDNESDAY, SEPTEMBER 12.

1. Underground Railway Communication in great Cities. By Colonel ROWLAND R. HAZARD	821
2. Transmission of Motion and Power. By J. WALTER PEARSE.....	823
3. An Annual Winding Clock, with Torsion Pendulum. By W. H. DOUGLAS	823
4. A new form of Air-compressor for Variable Pressures. By H. DAVEY, M.Inst.C.E.....	824
5. On controlling the direction of Rotation of a Dynamo. By A. WINTER...	824

SECTION H.—ANTHROPOLOGY.

THURSDAY, SEPTEMBER 6.

Address by Lieut.-General PITT-RIVERS, D.C.L., F.R.S., F.G.S., F.S.A., President of the Section	825
1. Report of the Committee for investigating the effects of different occupations and employments on the Physical Development of the Human Body	836
2. Second Report of the Committee for ascertaining and recording the localities in the British Islands in which evidences of the existence of Pre-historic Inhabitants of the country are found	836
3. The Constitutional Characteristics of those who dwell in large Towns, as relating to Degeneracy of Race. By G. B. BARRON, M.D., L.R.C.S.E., M.R.C.S., Hon. Surgeon-Major.....	836
4. The Physique of the Swiss as influenced by Race and by Media. By Dr. BEDDOE, F.R.S., V.P.A.I.	837
5. On Colour-blindness. By KARL GROSSMANN, M.D.....	838

FRIDAY, SEPTEMBER 7.

1. On Human Bones discovered by General Pitt-Rivers at Woodcuts, Rotherley, &c. By Dr. BEDDOE, F.R.S.....	839
2. Human Remains from Wiltshire. By J. G. GARSON, M.D., V.P.A.I.....	839
3. On a Method of investigating the Development of Institutions; applied to Laws of Marriage and Descent. By EDWARD B. TYLOR, F.R.S.	840
4. Australian Message-sticks and Messengers. By A. W. HOWITT, F.G.S	842
5. Social Regulations in Melanesia. By the Rev. R. H. CODRINGTON, D.D.	843

	Page
6. On the Funeral Rites and Ceremonies of the Nicobar Islanders. By E. H. MAN	844
7. Notes on the Shell-Mounds and Ossuaries of the Choptank River, Mary- land, U.S.A. By the Chevalier R. ELMER REYNOLDS	845

SATURDAY, SEPTEMBER 8.

1. Marriage Customs of the New Britain Group. By the Rev. BENJAMIN DANKS	847
2. Totem Clans and Star Worship. By GEORGE ST. CLAIR, F.G.S.	848
3. The Survival of Corporal Penance. By OSBERT H. HOWARTH.	849
4. Notes on Ghest-types. By Dr. G. W. HAMBLETON	849
5. Third Report of the Committee for investigating the Prehistoric Race in the Greek Islands	849
6. Fourth Report of the Committee for investigating and publishing reports on the physical characters, languages, and industrial and social condition of the North-Western Tribes of the Dominion of Canada.	849

MONDAY, SEPTEMBER 10.

1. Necklaces in relation to Prehistoric Commerce. By Miss A. W. BUCK- LAND	849

PLATES II., III., IV., AND V.

Illustrating the Report of the Committee for investigating the Microscopical Structure of the Older Rocks of Anglesey.

OBJECTS AND RULES

OF

THE ASSOCIATION.

OBJECTS.

THE ASSOCIATION contemplates no interference with the ground occupied by other institutions. Its objects are:—To give a stronger impulse and a more systematic direction to scientific inquiry,—to promote the intercourse of those who cultivate Science in different parts of the British Empire, with one another and with foreign philosophers,—to obtain a more general attention to the objects of Science, and a removal of any disadvantages of a public kind which impede its progress.

RULES.

Admission of Members and Associates.

All persons who have attended the first Meeting shall be entitled to become Members of the Association, upon subscribing an obligation to conform to its Rules.

The Fellows and Members of Chartered Literary and Philosophical Societies publishing Transactions, in the British Empire, shall be entitled, in like manner, to become Members of the Association.

The Officers and Members of the Councils, or Managing Committees, of Philosophical Institutions shall be entitled, in like manner, to become Members of the Association.

All Members of a Philosophical Institution recommended by its Council or Managing Committee shall be entitled, in like manner, to become Members of the Association.

Persons not belonging to such Institutions shall be elected by the General Committee or Council, to become Life Members of the Association, Annual Subscribers, or Associates for the year, subject to the approval of a General Meeting.

Compositions, Subscriptions, and Privileges.

LIFE MEMBERS shall pay, on admission, the sum of Ten Pounds. They shall receive *gratuitously* the Reports of the Association which may be published after the date of such payment. They are eligible to all the offices of the Association.

ANNUAL SUBSCRIBERS shall pay, on admission, the sum of Two Pounds, and in each following year the sum of One Pound. They shall receive

gratuitously the Reports of the Association for the year of their admission and for the years in which they continue to pay *without intermission* their Annual Subscription. By omitting to pay this subscription in any particular year, Members of this class (Annual Subscribers) *lose for that and all future years* the privilege of receiving the volumes of the Association *gratis*: but they may resume their Membership and other privileges at any subsequent Meeting of the Association, paying on each such occasion the sum of One Pound. They are eligible to all the Offices of the Association.

ASSOCIATES for the year shall pay on admission the sum of One Pound. They shall not receive *gratuitously* the Reports of the Association, nor be eligible to serve on Committees, or to hold any office.

The Association consists of the following classes:—

1. Life Members admitted from 1831 to 1845 inclusive, who have paid on admission Five Pounds as a composition.

2. Life Members who in 1846, or in subsequent years, have paid on admission Ten Pounds as a composition.

3. Annual Members admitted from 1831 to 1839 inclusive, subject to the payment of One Pound annually. [May resume their Membership after intermission of Annual Payment.]

4. Annual Members admitted in any year since 1839, subject to the payment of Two Pounds for the first year, and One Pound in each following year. [May resume their Membership after intermission of Annual Payment.]

5. Associates for the year, subject to the payment of One Pound.

6. Corresponding Members nominated by the Council.

And the Members and Associates will be entitled to receive the annual volume of Reports, *gratis*, or to *purchase* it at reduced (or Members') price, according to the following specification, viz.:—

1. *Gratis*.—Old Life Members who have paid Five Pounds as a composition for Annual Payments, and previous to 1845 a further sum of Two Pounds as a Book Subscription, or, since 1845, a further sum of Five Pounds.

New Life Members who have paid Ten Pounds as a composition.
Annual Members *who have not intermitted* their Annual Subscription.

2. *At reduced or Members' Price*, viz., two-thirds of the Publication Price.
—Old Life Members who have paid Five Pounds as a composition for Annual Payments, but no further sum as a Book Subscription.

Annual Members who have intermitted their Annual Subscription.
Associates for the year. [Privilege confined to the volume for that year only.]

3. Members may purchase (for the purpose of completing their sets) any of the volumes of the Reports of the Association up to 1874, of which more than 15 copies remain, at 2s. 6d. per volume.¹

Application to be made at the Office of the Association, 22 Albemarle Street, London, W.

Volumes not claimed within two years of the date of publication can only be issued by direction of the Council.

Subscriptions shall be received by the Treasurer or Secretaries.

¹ A few complete sets, 1831 to 1874, are on sale, at £10 the set.

Meetings.

The Association shall meet annually, for one week, or longer. The place of each Meeting shall be appointed by the General Committee two years in advance; and the arrangements for it shall be entrusted to the Officers of the Association.

General Committee.

The General Committee shall sit during the week of the Meeting, or longer, to transact the business of the Association. It shall consist of the following persons:—

CLASS A. PERMANENT MEMBERS.

1. Members of the Council, Presidents of the Association, and Presidents of Sections for the present and preceding years, with Authors of Reports in the Transactions of the Association.

2. Members who by the publication of Works or Papers have furthered the advancement of those subjects which are taken into consideration at the Sectional Meetings of the Association. *With a view of submitting new claims under this Rule to the decision of the Council, they must be sent to the Secretary at least one month before the Meeting of the Association. The decision of the Council on the claims of any Member of the Association to be placed on the list of the General Committee to be final.*

CLASS B. TEMPORARY MEMBERS.¹

1. Delegates nominated by the Corresponding Societies under the conditions hereinafter explained. *Claims under this Rule to be sent to the Secretary before the opening of the Meeting.*

2. Office-bearers for the time being, or delegates, altogether not exceeding three, from Scientific Institutions established in the place of Meeting. *Claims under this Rule to be approved by the Local Secretaries before the opening of the Meeting.*

3. Foreigners and other individuals whose assistance is desired, and who are specially nominated in writing, for the Meeting of the year, by the President and General Secretaries.

4. Vice-Presidents and Secretaries of Sections.

Organizing Sectional Committees.²

The Presidents, Vice-Presidents, and Secretaries of the several Sections are nominated by the Council, and have power to act until their names are submitted to the General Committee for election.

From the time of their nomination they constitute Organizing Committees for the purpose of obtaining information upon the Memoirs and Reports likely to be submitted to the Sections,³ and of preparing Reports

¹ Revised by the General Committee, 1884.

² Passed by the General Committee, Edinburgh, 1871.

³ *Notice to Contributors of Memoirs.*—Authors are reminded that, under an arrangement dating from 1871, the acceptance of Memoirs, and the days on which they are to be read, are now as far as possible determined by Organizing Committees for the several Sections *before the beginning of the Meeting.* It has therefore become necessary, in order to give an opportunity to the Committees of doing justice to the

thereon, and on the order in which it is desirable that they should be read, to be presented to the Committees of the Sections at their first meeting. The Sectional Presidents of former years are *ex officio* members of the Organizing Sectional Committees.¹

An Organizing Committee may also hold such preliminary meetings as the President of the Committee thinks expedient, but shall, under any circumstances, meet on the first Wednesday of the Annual Meeting, at 11 A.M., to nominate the first members of the Sectional Committee, if they shall consider it expedient to do so, and to settle the terms of their report to the General Committee, after which their functions as an Organizing Committee shall cease.²

Constitution of the Sectional Committees.³

On the first day of the Annual Meeting, the President, Vice-Presidents, and Secretaries of each Section having been appointed by the General Committee, these Officers, and those previous Presidents and Vice-Presidents of the Section who may desire to attend, are to meet, at 2 P.M., in their Committee Rooms, and enlarge the Sectional Committees by selecting individuals from among the Members (not Associates) present at the Meeting whose assistance they may particularly desire. The Sectional Committees thus constituted shall have power to add to their number from day to day.

The List thus formed is to be entered daily in the Sectional Minute-Book, and a copy forwarded without delay to the Printer, who is charged with publishing the same before 8 A.M. on the next day in the Journal of the Sectional Proceedings.

Business of the Sectional Committees.

Committee Meetings are to be held on the Wednesday at 2 P.M., on the following Thursday, Friday, Saturday,⁴ Monday, and Tuesday, from 10 to 11 A.M., punctually, for the objects stated in the Rules of the Association, and specified below.

The business is to be conducted in the following manner:—

1. The President shall call on the Secretary to read the minutes of the previous Meeting of the Committee.
- 2 No paper shall be read until it has been formally accepted by the

several Communications, that each Author should prepare an Abstract of his Memoir, of a length suitable for insertion in the published Transactions of the Association, and that he should send it, together with the original Memoir, by book-post, on or before....., addressed thus—'General Secretaries, British Association, 22 Albemarle Street, London, W. For Section'. If it should be inconvenient to the Author that his paper should be read on any particular days, he is requested to send information thereof to the Secretaries in a separate note. Authors who send in their MSS. three complete weeks before the Meeting, and whose papers are accepted, will be furnished, before the Meeting, with printed copies of their Reports and Abstracts. No Report, Paper, or Abstract can be inserted in the Annual Volume unless it is handed either to the Recorder of the Section or to the Secretary, before the conclusion of the Meeting.

¹ Added by the General Committee, Sheffield, 1879.

² Revised by the General Committee, Swansea, 1880.

³ Passed by the General Committee, Edinburgh, 1871.

⁴ The meeting on Saturday was made optional by the General Committee at Southport, 1883.

Committee of the Section, and entered on the minutes accordingly.

3. Papers which have been reported on unfavourably by the Organizing Committees shall not be brought before the Sectional Committees.¹

At the first meeting, one of the Secretaries will read the Minutes of last year's proceedings, as recorded in the Minute-Book, and the Synopsis of Recommendations adopted at the last Meeting of the Association and printed in the last volume of the Transactions. He will next proceed to read the Report of the Organizing Committee.² The list of Communications to be read on Thursday shall be then arranged, and the general distribution of business throughout the week shall be provisionally appointed. At the close of the Committee Meeting the Secretaries shall forward to the Printer a List of the Papers appointed to be read. The Printer is charged with publishing the same before 8 A.M. on Thursday in the Journal.

On the second day of the Annual Meeting, and the following days, the Secretaries are to correct, on a copy of the Journal, the list of papers which have been read on that day, to add to it a list of those appointed to be read on the next day, and to send this copy of the Journal as early in the day as possible to the Printer, who is charged with printing the same before 8 A.M. next morning in the Journal. It is necessary that one of the Secretaries of each Section (generally the Recorder) should call at the Printing Office and revise the proof each evening.

Minutes of the proceedings of every Committee are to be entered daily in the Minute-Book, which should be confirmed at the next meeting of the Committee.

Lists of the Reports and Memoirs read in the Sections are to be entered in the Minute-Book daily, which, with *all Memoirs and Copies or Abstracts of Memoirs furnished by Authors, are to be forwarded, at the close of the Sectional Meetings, to the Secretary.*

The Vice-Presidents and Secretaries of Sections become *ex officio* temporary Members of the General Committee (*vide* p. xxxiii), and will receive, on application to the Treasurer in the Reception Room, Tickets entitling them to attend its Meetings.

The Committees will take into consideration any suggestions which may be offered by their Members for the advancement of Science. They are specially requested to review the recommendations adopted at preceding Meetings, as published in the volumes of the Association and the communications made to the Sections at this Meeting, for the purposes of selecting definite points of research to which individual or combined exertion may be usefully directed, and branches of knowledge on the state and progress of which Reports are wanted; to name individuals or Committees for the execution of such Reports or researches; and to state whether, and to what degree, these objects may be usefully advanced by the appropriation of the funds of the Association, by application to Government, Philosophical Institutions, or Local Authorities.

In case of appointment of Committees for special objects of Science, it is expedient that *all Members of the Committee should be named, and one of them appointed to act as Chairman, who shall have notified personally*

¹ These rules were adopted by the General Committee, Plymouth, 1877.

² This and the following sentence were added by the General Committee, Edinburgh, 1871.

or in writing his willingness to accept the office, the Chairman to have the responsibility of receiving and disbursing the grant (if any has been made) and securing the presentation of the Report in due time; and, further, it is expedient that one of the members should be appointed to act as Secretary, for insuring attention to business.

That it is desirable that the number of Members appointed to serve on a Committee should be as small as is consistent with its efficient working.

That a tabular list of the Committees appointed on the recommendation of each Section should be sent each year to the Records of the several Sections, to enable them to fill in the statement whether the several Committees appointed on the recommendation of their respective Sections had presented their reports.

That on the proposal to recommend the appointment of a Committee for a special object of science having been adopted by the Sectional Committee, the number of Members of such Committee be then fixed, but that the Members to serve on such Committee be nominated and selected by the Sectional Committee at a subsequent meeting.¹

Committees have power to add to their number persons whose assistance they may require.

The recommendations adopted by the Committees of Sections are to be registered in the Forms furnished to their Secretaries, and one Copy of each is to be forwarded, without delay, to the Secretary for presentation to the Committee of Recommendations. *Unless this be done, the Recommendations cannot receive the sanction of the Association.*

N.B.—Recommendations which may originate in any one of the Sections must first be sanctioned by the Committee of that Section before they can be referred to the Committee of Recommendations or confirmed by the General Committee.

The Committees of the Sections shall ascertain whether a Report has been made by every Committee appointed at the previous Meeting to whom a sum of money has been granted, and shall report to the Committee of Recommendations in every case where no such Report has been received.²

Notices regarding Grants of Money.

Committees and individuals, to whom grants of money have been entrusted by the Association for the prosecution of particular researches in science, are required to present to each following Meeting of the Association a Report of the progress which has been made; and the Chairman of a Committee to whom a money grant has been made must (previously to the next Meeting of the Association) forward to the General Secretaries or Treasurer a statement of the sums which have been expended, and the balance which remains disposable on each grant.

Grants of money sanctioned at any one Meeting of the Association expire a week before the opening of the ensuing Meeting; nor is the Treasurer authorized, after that date, to allow any claims on account of such grants, unless they be renewed in the original or a modified form by the General Committee.

No Committee shall raise money in the name or under the auspices

¹ Revised by the General Committee, Bath, 1888.

² Passed by the General Committee at Sheffield, 1879.

of the British Association without special permission from the General Committee to do so ; and no money so raised shall be expended except in accordance with the rules of the Association.

In each Committee, the Chairman is the only person entitled to call on the Treasurer, Professor A. W. Williamson, 17 Buckingham Street, London, W.C., for such portion of the sums granted as may from time to time be required.

In grants of money to Committees, the Association does not contemplate the payment of personal expenses to the members.

In all cases where additional grants of money are made for the continuation of Researches at the cost of the Association, the sum named is deemed to include, as a part of the amount, whatever balance may remain unpaid on the former grant for the same object.

All Instruments, Papers, Drawings, and other property of the Association are to be deposited at the Office of the Association, 22 Albemarle Street, Piccadilly, London, W., when not employed in carrying on scientific inquiries for the Association.

Business of the Sections.

The Meeting Room of each Section is opened for conversation from 10 to 11 daily. *The Section Rooms and approaches thereto can be used for no notices, exhibitions, or other purposes than those of the Association.*

At 11 precisely the Chair will be taken,¹ and the reading of communications, in the order previously made public, commenced. At 3 P.M. the Sections will close.

Sections may, by the desire of the Committees, divide themselves into Departments, as often as the number and nature of the communications delivered in may render such divisions desirable.

A Report presented to the Association, and read to the Section which originally called for it, may be read in another Section, at the request of the Officers of that Section, with the consent of the Author.

Duties of the Doorkeepers.

- 1.—To remain constantly at the Doors of the Rooms to which they are appointed during the whole time for which they are engaged.
- 2.—To require of every person desirous of entering the Rooms the exhibition of a Member's, Associate's, or Lady's Ticket, or Reporter's Ticket, signed by the Treasurer, or a Special Ticket signed by the Secretary.
- 3.—Persons unprovided with any of these Tickets can only be admitted to any particular Room by order of the Secretary in that Room.

No person is exempt from these Rules, except those Officers of the Association whose names are printed in the programme, p. 1.

Duties of the Messengers.

To remain constantly at the Rooms to which they are appointed during the whole time for which they are engaged, except when employed on messages by one of the Officers directing these Rooms.

¹ The sectional meetings on Saturday and on Wednesday may begin at any time which may be fixed by the Committee, not earlier than 10 or later than 11. *Passed by the General Committee at Bath, 1888.

Committee of Recommendations.

The General Committee shall appoint at each Meeting a Committee, which shall receive and consider the Recommendations of the Sectional Committees, and report to the General Committee the measures which they would advise to be adopted for the advancement of Science.

All Recommendations of Grants of Money, Requests for Special Researches, and Reports on Scientific Subjects shall be submitted to the Committee of Recommendations, and not taken into consideration by the General Committee unless previously recommended by the Committee of Recommendations.

Corresponding Societies.¹

(1.) Any Society is eligible to be placed on the List of Corresponding Societies of the Association which undertakes local scientific investigations, and publishes notices of the results.

(2.) Applications may be made by any Society to be placed on the List of Corresponding Societies. Application must be addressed to the Secretary on or before the 1st of June preceding the Annual Meeting at which it is intended they should be considered, and must be accompanied by specimens of the publications of the results of the local scientific investigations recently undertaken by the Society.

(3.) A Corresponding Societies Committee shall be annually nominated by the Council and appointed by the General Committee for the purpose of considering these applications, as well as for that of keeping themselves generally informed of the annual work of the Corresponding Societies, and of superintending the preparation of a list of the papers published by them. This Committee shall make an annual report to the General Committee, and shall suggest such additions or changes in the List of Corresponding Societies as they may think desirable.

(4.) Every Corresponding Society shall return each year, on or before the 1st of June, to the Secretary of the Association, a schedule, properly filled up, which will be issued by the Secretary of the Association, and which will contain a request for such particulars with regard to the Society as may be required for the information of the Corresponding Societies Committee.

(5.) There shall be inserted in the Annual Report of the Association a list, in an abbreviated form, of the papers published by the Corresponding Societies during the past twelve months which contain the results of the local scientific work conducted by them; those papers only being included which refer to subjects coming under the cognisance of one or other of the various Sections of the Association.

(6.) A Corresponding Society shall have the right to nominate any one of its members, who is also a Member of the Association, as its delegate to the Annual Meeting of the Association, who shall be for the time a Member of the General Committee.

Conference of Delegates of Corresponding Societies.

(7.) That the Conference of Delegates of Corresponding Societies be empowered to send recommendations to the Committee of Recommendations for their consideration, and for report to the General Committee.'

¹ Passed by the General Committee, 1884.

(8.) The Delegates of the various Corresponding Societies shall constitute a Conference, of which the Chairman, Vice-Chairmen, and Secretaries shall be annually nominated by the Council, and appointed by the General Committee, and of which the members of the Corresponding Societies Committee shall be *ex officio* members.

(9.) The Conference of Delegates shall be summoned by the Secretaries to hold one or more meetings during each Annual Meeting of the Association, and shall be empowered to invite any Member or Associate to take part in the meetings.

(10.) The Secretaries of each Section shall be instructed to transmit to the Secretaries of the Conference of Delegates copies of any recommendations forwarded by the Presidents of Sections to the Committee of Recommendations bearing upon matters in which the co-operation of Corresponding Societies is desired; and the Secretaries of the Conference of Delegates shall invite the authors of these recommendations to attend the meetings of the Conference and give verbal explanations of their objects and of the precise way in which they would desire to have them carried into effect.

(11.) It will be the duty of the Delegates to make themselves familiar with the purport of the several recommendations brought before the Conference, in order that they and others who take part in the meetings may be able to bring those recommendations clearly and favourably before their respective Societies. The Conference may also discuss propositions bearing on the promotion of more systematic observation and plans of operation, and of greater uniformity in the mode of publishing results.

Local Committees.

Local Committees shall be formed by the Officers of the Association to assist in making arrangements for the Meetings.

Local Committees shall have the power of adding to their numbers those Members of the Association whose assistance they may desire.

Officers.

A President, two or more Vice-Presidents, one or more Secretaries, and a Treasurer shall be annually appointed by the General Committee.

Council.

In the intervals of the Meetings, the affairs of the Association shall be managed by a Council appointed by the General Committee. The Council may also assemble for the despatch of business during the week of the Meeting.

(1) The Council shall consist of ¹

1. The Trustees.
2. The past Presidents.
3. The President and Vice-Presidents for the time being.
4. The President and Vice-Presidents elect.
5. The past and present General Treasurers, General and Assistant General Secretaries.

¹ Passed by the General Committee, Belfast, 1874.

6. The Local Treasurer and Secretaries for the ensuing Meeting.

7. Ordinary Members.

(2) The Ordinary Members shall be elected annually from the General Committee.

(3) There shall be not more than twenty-five Ordinary Members, of whom not more than twenty shall have served on the Council, as Ordinary Members, in the previous year.

In order to carry out the foregoing rule, the following Ordinary Members of the outgoing Council shall at each annual election be ineligible for nomination:—1st, those who have served on the Council for the greatest number of consecutive years; and, 2nd, those who, being resident in or near London, have attended the fewest number of Meetings during the year—observing (as nearly as possible) the proportion of three by seniority to two by least attendance.

(5) The Council shall submit to the General Committee in their Annual Report the names of the Members of General Committee whom they recommend for election as Members of Council.

(6) The Election shall take place at the same time as that of the Officers of the Association.

Papers and Communications.

The Author of any paper or communication shall be at liberty to reserve his right of property therein.

Accounts.

The Accounts of the Association shall be audited annually, by Auditors appointed by the General Committee.

Table showing the Places and Times of Meeting of the British Association, with Presidents, Vice-Presidents, and Local Secretaries, from its Commencement.

SOUTHAMPTON, August 23, 1882.

ARTHUR CAYLEY, Esq., M.A., D.C.L., LL.D., F.R.S.,
V.P.R.A.S., Sedlerian Professor of Pure Mathematics
in the University of Cambridge.....
SOUTHPORT, September 19, 1883.

The RIGHT HON. LORD RAYLEIGH, M.A., D.C.L.,
LL.D., F.R.S., F.R.A.S., F.R.G.S., Professor of Experi-
mental Physics in the University of Cambridge.....
MONTREAL, August 27, 1884.

VICE-PRESIDENTS.

The Right Hon. the Earl of Jersey.....
The Mayor of Swansea.....
The Hon. Sir W. R. Grove, M.A., D.C.L., F.R.S.....
H. Hussey Vivian, Esq., M.P., F.G.S.....
L. Ll. Dilwyn, Esq., M.P., F.L.S., F.G.S.....
J. Gwyn Jeffreys, Esq., LL.D., F.R.S., F.L.S., Treas. G.S., F.R.G.S.....

His Grace the Archbishop of York, D.D., F.R.S.....
The Right Hon. the Lord Mayor of York.....
The Right Hon. Lord Houghton, D.C.L., F.R.S., F.R.G.S.....
The Venerable Archdeacon Creyke, M.A.....
The Hon. Sir W. R. Grove, M.A., D.C.L., F.R.S.....
Professor G. G. Stokes, M.A., D.C.L., LL.D., Sec. R.S.....
Sir John Hawkshaw, C.E., F.R.S., F.G.S., F.R.G.S.....
Allen Thomson, Esq., M.D., LL.D., F.R.S.L. & E.....
Professor Allman, M.D., LL.D., F.R.S.L. & E., F.L.S.....

The Right Hon. the Lord Mount-Temple.....
Captain Sir F. J. Evans, K.C.B., F.R.S., F.R.A.S., F.R.G.S., Hydro-
grapher to the Admiralty.....
F. A. Abel, Esq., C.B., F.R.S., V.P.C.S., Director of the Chemical
Establishment of the War Department.....
Professor De Chaumont, M.D., F.R.S.....
Major-General A. C. Cooke, R.E., C.B., F.R.G.S., Director-General of
the Ordnance Survey.....
Professor Prestwich, M.A., F.R.S., F.G.S., F.C.S.....
Philip Lutley Sclater, Esq., M.A., Ph.D., F.R.S., F.L.S., F.G.S.....

The Right Hon. the Earl of Derby, M.A., LL.D., F.R.S., F.R.G.S.....
The Right Hon. the Earl of Crawford and Balcarres, LL.D., F.R.S.,
F.R.A.S.....
Principal J. W. Dawson, C.M.G., M.A., LL.D., F.R.S., F.G.S.....
J. G. Greenwood, Esq., LL.D., Vice-Chancellor of the Victoria University
Professor H. E. Roscoe, Ph.D., LL.D., F.R.S., F.C.S.....

His Excellency the Governor-General of Canada, G.C.M.G., LL.D.....
The Right Hon. Sir John Alexander Macdonald, K.C.B., D.C.L., LL.D.....
The Right Hon. Sir Lyon Playfair, K.C.B., M.P., Ph.D., LL.D., F.R.S.L.
& E., F.C.S.....
The Hon. Sir Alexander Tilloch Galt, G.C.M.G.....
The Hon. Sir Charles Tupper, K.C.M.G.....
Chief Justice Sir A. A. Dorian, C.M.G.....
Principal Sir William Dawson, C.M.G., M.A., LL.D., F.R.S., F.G.S.....
The Hon. Dr. Chauveau.....
Professor Edward Frankland, M.D., D.C.L., Ph.D., LL.D., F.R.S., F.C.S.
W. H. Hingston, Esq., M.D., D.C.L., L.R.C.S.E.....
Thomas Sterry Hunt, Esq., M.A., D.Sc., LL.D., F.R.S.....

LOCAL SECRETARIES.

W. Morgan Esq., Ph.D., F.C.S.
James Strick, Esq.

Rev. Thomas Adams, M.A.
Tempest Anderson, Esq., M.D. B.Sc

C. W. A. Jellicoe, Esq.
John E. Le Feuvre, Esq.
Morris Miles, Esq.

J. H. Ellis, Esq.
Dr. Vernon.
T. W. Willis, Esq.

S. E. Dawson, Esq.
R. A. Ramsay, Esq.
S. Rivard, Esq.
S. C. Stevenson, Esq.
Thos. White, Esq., M.P.

The RIGHT HON. SIR LYON PLAYFAIR, K.O.B., M.P.,
Ph.D., LL.D., F.R.S. L. & E., F.C.S.....
ABERDEEN, September 9, 1885.

SIR J. WILLIAM DAWSON, C.M.G., M.A., LL.D., F.R.S.,
F.G.S., Principal and Vice-Chancellor of McGill Uni-
versity, Montreal, Canada
BIRMINGHAM, September 1, 1886.

SIR H. E. ROSCOE, M.P., D.C.L., LL.D., Ph.D., F.R.S.,
V.P.O.S.....
MANCHESTER, August 31, 1887.

SIR FREDERICK J. BRAMWELL, D.C.L., F.R.S.,
M.Inst.C.E.
BATH, September 5, 1888.

His Grace the Duke of Richmond and Gordon, K.G., D.C.L., Chancellor
of the University of Aberdeen
The Right Hon. the Earl of Aberdeen, LL.D., Lord-Lieutenant of
Aberdeenshire
The Right Hon. the Earl of Crawford and Balcarres, M.A., LL.D.,
F.R.S., F.R.A.S.
James Matthews, Esq., Lord Provost of the City of Aberdeen
Professor Sir William Thomson, M.A., LL.D., F.R.S. L. & E., F.R.A.S.
Alexander Bain, Esq., M.A., LL.D., Rector of the University of
Aberdeen
The Very Rev. Principal Pirie, D.D., Vice-Chancellor of the University
of Aberdeen
Professor W. H. Flower, LL.D., F.R.S., F.L.S., Pres. Z.S., F.G.S.,
Director of the Natural History Museum, London
Professor John Struthers, M.D., LL.D.

The Right Hon. the Earl of Bradford, Lord-Lieutenant of Shropshire.
The Right Hon. Lord Leigh, D.C.L., Lord-Lieutenant of Warwickshire.
The Right Hon. Lord Norton, K.C.M.G.
The Right Hon. Lord Wrottesley, Lord-Lieutenant of Staffordshire ..
The Right Rev. the Lord Bishop of Worcester, D.D.
Thomas Martineau, Esq., Mayor of Birmingham.
Professor G. G. Stokes, M.A., D.C.L., LL.D., Pres. R.S.
Professor W. A. Tilden, D.Sc., F.R.S., F.G.S.
Rev. A. R. Vardy, M.A.
Rev. H. W. Watson, D.Sc., F.R.S.

His Grace the Duke of Devonshire, K.G., M.A., LL.D., F.R.S., F.G.S.,
F.R.G.S.
The Right Hon. the Earl of Derby, K.G., M.A., LL.D., F.R.S., F.R.G.S.
The Right Rev. the Lord Bishop of Manchester, D.D.
The Right Rev. the Bishop of Salford
The Right Rev. the Mayor of Manchester
The Right Worshipful the Mayor of Salford
The Vice-Chancellor of the Victoria University
The Principal of the Owens College
Sir William Roberts, B.A., M.D., F.R.S.
Thomas Ashton, Esq., J.P., D.L.
Oliver Heywood, Esq., J.P., D.L.
James Prescott Joule, Esq., D.C.L., LL.D., F.R.S., F.R.S.E., F.C.S.

The Right Hon. the Earl of Cork and Orrery, Lord Lieutenant of Somer-
set
The Most Noble the Marquis of Bath
The Right Hon. and Right Rev. the Lord Bishop of Bath and Wells, D.D.
The Right Rev. the Bishop of Clifton, D.D.
The Right Worshipful the Mayor of Bath

Sir F. A. Abel, O.B., D.O.L., F.R.S., V.P.C.S.
The Venerable the Archdeacon of Bath, M.A.
The Rev. Leonard Blomefield, M.A., F.L.S., F.G.S.
Professor Michael Foster, M.A., M.D., LL.D., Sec. R.S., F.L.S., F.C.S. ...
W. S. Gore-Langton, Esq., J.P., D.L.
H. D. Skrine, Esq., J.P., D.L.
E. R. Wodehouse, Esq., M.P.
Colonel R. P. Laurie, O.B., M.P.
Jerom Murch, Esq., J.P., D.L.

J. W. Crombie, Esq., M.A.
Angus Fraser, Esq., M.A., M.D., F.C.S
Professor G. Pirie, M.A.

J. Barham Carslake, Esq.
Rev. H. W. Crosskey, LL.D., F.G.S.
Charles J. Hart, Esq.

F. J. Faraday, Esq., F.L.S., F.S.S.
Charles Hopkinson, Esq., B.Sc.
Professor A. Milnes Marshall, M.A., M.D.,
D.Sc., F.R.S.
Professor A. H. Young, M.B., F.R.C.S:

W. Pumphrey, Esq.
J. L. Stothert, Esq., M.Inst.C.E.
B. H. Watts, Esq.

Presidents and Secretaries of the Sections of the Association.

Date and Place	Presidents	Secretaries
MATHEMATICAL AND PHYSICAL SCIENCES.		
COMMITTEE OF SCIENCES, I.—MATHEMATICS AND GENERAL PHYSICS.		
1832. Oxford.....	Davies Gilbert, D.C.L., F.R.S.	Rev. H. Coddington.
1833. Cambridge	Sir D. Brewster, F.R.S.	Prof. Forbes.
1834. Edinburgh	Rev. W. Whewell, F.R.S.	Prof. Forbes, Prof. Lloyd.
SECTION A.—MATHEMATICS AND PHYSICS.		
1835. Dublin.....	Rev. Dr. Robinson	Prof. Sir W. R. Hamilton, Prof. Wheatstone.
1836. Bristol.....	Rev. William Whewell, F.R.S.	Prof. Forbes, W. S. Harris, F. W. Jerrard.
1837. Liverpool...	Sir D. Brewster, F.R.S.	W. S. Harris, Rev. Prof. Powell, Prof. Stevelly.
1838. Newcastle	Sir J. F. W. Herschel, Bart., F.R.S.	Rev. Prof. Chevallier, Major Sabine, Prof. Stevelly.
1839. Birmingham	Rev. Prof. Whewell, F.R.S....	J. D. Chance, W. Snow Harris, Prof. Stevelly.
1840. Glasgow ...	Prof. Forbes, F.R.S.....	Rev. Dr. Forbes, Prof. Stevelly, Arch. Smith.
1841. Plymouth	Rev. Prof. Lloyd, F.R.S.	Prof. Stevelly.
1842. Manchester	Very Rev. G. Peacock, D.D., F.R.S.	Prof. McCulloch, Prof. Stevelly, Rev. W. Scoresby.
1843. Cork.....	Prof. McCulloch, M.R.I.A. ...	J. Nott, Prof. Stevelly.
1844. York.....	The Earl of Rosse, F.R.S. ...	Rev. Wm. Hey, Prof. Stevelly.
1845. Cambridge	The Very Rev. the Dean of Ely.	Rev. H. Goodwin, Prof. Stevelly, G. G. Stokes.
1846. Southamp- ton.	Sir John F. W. Herschel, Bart., F.R.S.	John Drew, Dr. Stevelly, G. G. Stokes.
1847. Oxford.....	Rev. Prof. Powell, M.A., F.R.S.	Rev. H. Price, Prof. Stevelly, G. G. Stokes.
1848. Swansea ...	Lord Wrottesley, F.R.S.	Dr. Stevelly, G. G. Stokes.
1849. Birmingham	William Hopkins, F.R.S.....	Prof. Stevelly, G. G. Stokes, W. Ridout Wills.
1850. Edinburgh	Prof. J. D. Forbes, F.R.S., Sec. R.S.E.	W. J. Macquorn Rankine, Prof. Smyth, Prof. Stevelly, Prof. G. G. Stokes.
1851. Ipswich ...	Rev. W. Whewell, D.D., F.R.S.	S. Jackson, W. J. Macquorn Rankine, Prof. Stevelly, Prof. G. G. Stokes.
1852. Belfast.....	Prof. W. Thomson, M.A., F.R.S. L. & E.	Prof. Dixon, W. J. Macquorn Rankine, Prof. Stevelly, J. Tyndall.
1853. Hull.....	The Very Rev. the Dean of Ely, F.R.S.	B. Blaydes Haworth, J. D. Sollitt, Prof. Stevelly, J. Welsh.
1854. Liverpool...	Prof. G. G. Stokes, M.A., Sec. R.S.	J. Hartnup, H. G. Puckle, Prof. Stevelly, J. Tyndall, J. Welsh.
1855. Glasgow ...	Rev. Prof. Kelland, M.A., F.R.S. L. & E.	Rev. Dr. Forbes, Prof. D. Gray, Prof. Tyndall.
1856. Cheltenham	Rev. R. Walker, M.A., F.R.S.	C. Brooke, Rev. T. A. Southwood, Prof. Stevelly, Rev. J. C. Turnbull.
1857. Dublin.....	Rev. T. R. Robinson, D.D., F.R.S., M.R.I.A.	Prof. Curtis, Prof. Hennessy, P. A. Ninnis, W. J. Macquorn Rankine, Prof. Stevelly.
1858. Leeds	Rev. W. Whewell, D.D., V.P.R.S.	Rev. S. Earnshaw, J. P. Hennessy, Prof. Stevelly, H. J. S. Smith, Prof. Tyndall.

Date and Place	Presidents	Secretaries
1859. Aberdeen...	The Earl of Rosse, M.A., K.P., F.R.S.	J. P. Hennessy, Prof. Maxwell, H. J. S. Smith, Prof. Stevelly.
1860. Oxford.....	Rev. B. Price, M.A., F.R.S....	Rev. G. C. Bell, Rev. T. Rennison, Prof. Stevelly.
•1861. Manchester	G. B. Airy, M.A., D.C.L., F.R.S.	Prof. R. B. Clifton, Prof. H. J. S. Smith, Prof. Stevelly.
1862. Cambridge	Prof. G. G. Stokes, M.A., F.R.S.	Prof. R. B. Clifton, Prof. H. J. S. Smith, Prof. Stevelly.
•1863. Newcastle	Prof. W. J. Macquorn Rankine, C.E., F.R.S.	Rev. N. Ferrers, Prof. Fuller, F. •Jenkin, Prof. Stevelly, Rev. C. T. Whitley.
1864. Bath.....	Prof. Cayley, M.A., F.R.S., F.R.A.S.	Prof. Fuller, F. Jenkin, Rev. G. Buckle, Prof. Stevelly.
1865. Birmingham	W. Spottiswoode, M.A., F.R.S., F.R.A.S.	Rev. T. N. Hutchinson, F. Jenkin, G. S. Mathews, Prof. H. J. S. Smith, J. M. Wilson.
•1866. Nottingham	Prof. Wheatstone, D.C.L., F.R.S.	Fleeming Jenkin, Prof. H. J. S. Smith, Rev. S. N. Swann.
1867. Dundee ...	Prof. Sir W. Thomson, D.C.L., F.R.S.	Rev. G. Buckle, Prof. G. C. Foster, Prof. Fuller, Prof. Swan.
•1868. Norwich ...	Prof. J. Tyndall, LL.D., F.R.S.	Prof. G. C. Foster, Rev. R. Harley, R. B. Hayward.
1869. Exeter.....	Prof. J. J. Sylvester, LL.D., F.R.S.	Prof. G. C. Foster, R. B. Hayward, W. K. Clifford.
1870. Liverpool...	J. Clerk Maxwell, M.A., LL.D., F.R.S.	Prof. W. G. Adams, W. K. Clifford, Prof. G. C. Foster, Rev. W. Allen Whitworth.
1871. Edinburgh	Prof. P. G. Tait, F.R.S.E. ...	Prof. W. G. Adams, J. T. Bottomley, Prof. W. K. Clifford, Prof. J. D. Everett, Rev. R. Harley.
1872. Brighton ...	W. De La Rue, D.C.L., F.R.S.	Prof. W. K. Clifford, J. W. L. Glaisher, Prof. A. S. Herschel, G. F. Rodwell.
1873. Bradford ...	Prof. H. J. S. Smith, F.R.S.	Prof. W. K. Clifford, Prof. Forbes, J. W. L. Glaisher, Prof. A. S. Herschel.
1874. Belfast.....	Rev. Prof. J. H. Jellett, M.A., M.R.I.A.	J. W. L. Glaisher, Prof. Herschel, Randal Nixon, J. Perry, G. F. Rodwell.
1875. Bristol.....	Prof. Balfour Stewart, M.A., LL.D., F.R.S.	Prof. W. F. Barrett, J. W. L. Glaisher, C. T. Hudson, G. F. Rodwell.
1876. Glasgow ...	Prof. Sir W. Thomson, M.A., D.C.L., F.R.S.	Prof. W. F. Barrett, J. T. Bottomley, Prof. G. Forbes, J. W. L. Glaisher, T. Muir.
1877. Plymouth...	Prof. G. C. Foster, B.A., F.R.S., Pres. Physical Soc.	Prof. W. F. Barrett, J. T. Bottomley, J. W. L. Glaisher, F. G. Landon.
1878. Dublin.....	Rev. Prof. Salmon, D.D., D.C.L., F.R.S.	Prof. J. Casey, G. F. Fitzgerald, J. W. L. Glaisher, Dr. O. J. Lodge.
1879. Sheffield ...	George Johnstone Stoney, M.A., F.R.S.	A. H. Allen, J. W. L. Glaisher, Dr. O. J. Lodge, D. MacAlister.
1880. Swansea ...	Prof. W. Grylls Adams, M.A., F.R.S.	W. E. Ayrton, J. W. L. Glaisher, Dr. O. J. Lodge, D. MacAlister.
1881. York.....	Prof. Sir W. Thomson, M.A., LL.D., D.C.L., F.R.S.	Prof. W. E. Ayrton, Prof. O. J. Lodge, D. MacAlister, Rev. W. Routh.
1882. Southamp- ton.	Rt. Hon. Prof. Lord Rayleigh, M.A., F.R.S.	W. M. Hicks, Prof. O. J. Lodge, D. MacAlister, Rev. G. Richard- son.
1883. Southport	Prof. O. Henrici, Ph.D., F.R.S.,	W. M. Hicks, Prof. O. J. Lodge, D. MacAlister, Prof. R. C. Rowe.
1884. Montreal ...	Prof. Sir W. Thomson, M.A., LL.D., D.C.L. F.R.S	C. Carpmal, W. M. Hicks, Prof. A. Johnson, Prof. O. J. Lodge, Dr. D. MacAlister.

Date and Place	Presidents	Secretaries
1885. Aberdeen...	Prof. G. Chrystal, M.A., F.R.S.E.	R. E. Baynes, R. T. Glazebrook, Prof. W. M. Hicks, Prof. W. Ingram.
1886. Birmingham	Prof. G. H. Darwin, M.A., LL.D., F.R.S.	R. E. Baynes, R. T. Glazebrook, Prof. J. H. Poynting, W. N. Shaw.
1887. Manchester	Prof. Sir R. S. Ball, M.A., LL.D., F.R.S.	R. E. Baynes, R. T. Glazebrook, Prof. H. Lamb, W. N. Shaw.
1888. Bath	Prof. G. F. Fitzgerald, M.A., F.R.S.	R. E. Baynes, R. T. Glazebrook, A. Lodge, W. N. Shaw.

CHEMICAL SCIENCE.

COMMITTEE OF SCIENCES, II.—CHEMISTRY, MINERALOGY.

1832. Oxford	John Dalton, D.C.L., F.R.S.	James F. W. Johnston.
1833. Cambridge	John Dalton, D.C.L., F.R.S.	Prof. Miller.
1834. Edinburgh	Dr. Hope	Mr. Johnston, Dr. Christison.

SECTION B.—CHEMISTRY AND MINERALOGY.

1835. Dublin	Dr. T. Thomson, F.R.S.	Dr. Apjohn, Prof. Johnston.
1836. Bristol	Rev. Prof. Cumming	Dr. Apjohn, Dr. C. Henry, W. Hera- path.
1837. Liverpool...	Michael Faraday, F.R.S.....	Prof. Johnston, Prof. Miller, Dr. Reynolds.
1838. Newcastle	Rev. William Whewell, F.R.S.	Prof. Miller, H. L. Pattinson, Thomas Richardson.
1839. Birmingham	Prof. T. Graham, F.R.S.	Dr. Golding Bird, Dr. J. B. Melson.
1840. Glasgow ...	Dr. Thomas Thomson, F.R.S.	Dr. R. D. Thomson, Dr. T. Clark, Dr. L. Playfair.
1841. Plymouth...	Dr. Daubeny, F.R.S.	J. Prideaux, Robert Hunt, W. M. Tweedy.
1842. Manchester	John Dalton, D.C.L., F.R.S.	Dr. L. Playfair, R. Hunt, J. Graham.
1843. Cork	Prof. Apjohn, M.R.I.A.....	R. Hunt, Dr. Sweeny.
1844. York	Prof. T. Graham, F.R.S.	Dr. L. Playfair, E. Solly, T. H. Barker.
1845. Cambridge	Rev. Prof. Cumming	R. Hunt, J. P. Joule, Prof. Miller, E. Solly.
1846. Southamp- ton	Michael Faraday, D.C.L., F.R.S.	Dr. Miller, R. Hunt, W. Randall.
1847. Oxford	Rev. W. V. Harcourt, M.A., F.R.S.	B. C. Brodie, R. Hunt, Prof. Solly.
1848. Swansea ...	Richard Phillips, F.R.S.	T. H. Henry, R. Hunt, T. Williams.
1849. Birmingham	John Percy, M.D., F.R.S.....	R. Hunt, G. Shaw.
1850. Edinburgh	Dr. Christison, V.P.R.S.E.	Dr. Anderson, R. Hunt, Dr. Wilson.
1851. Ipswich ...	Prof. Thomas Graham, F.R.S.	T. J. Pearsall, W. S. Ward.
1852. Belfast	Thomas Andrews, M.D., F.R.S.	Dr. Gladstone, Prof. Hodges, Prof. Ronalds.
1853. Hull	Prof. J. F. W. Johnston, M.A., F.R.S.	H. S. Blundell, Prof. R. Hunt, T. J. Pearsall.
1854. Liverpool	Prof. W. A. Miller, M.D., F.R.S.	Dr. Edwards, Dr. Gladstone, Dr. Price.
1855. Glasgow ...	Dr. Lyon Playfair, C.B., F.R.S.	Prof. Frankland, Dr. H. E. Roscoe.
1856. Cheltenham	Prof. B. C. Brodie, F.R.S. ...	J. Horsley, P. J. Worsley, Prof. Voelcker.
1857. Dublin	Prof. Apjohn, M.D., F.R.S., M.R.I.A.	Dr. Davy, Dr. Gladstone, Prof. Sul- tman.
1858. Leeds	Sir J. F. W. Herschel, Bart., D.C.L.	Dr. Gladstone, W. Odling, R. Rey- nolds.
1859. Aberdeen...	Dr. Lyon Playfair, C.B., F.R.S.	J. S. Brazier, Dr. Gladstone, G. D. Liveing, Dr. Odling.

Date and Place	Presidents	Secretaries
1860. Oxford.....	Prof. B. C. Brodie, F.R.S.....	A. Vernon Harcourt, G. D. Liveing, A. B. Northcote.
1861. Manchester	Prof. W.A. Miller, M.D., F.R.S.	A. Vernon Harcourt, G. D. Liveing.
1862. Cambridge	Prof. W.A. Miller, M.D., F.R.S.	H. W. Elphinstone, W. Odling, Prof. Roscoe.
1863. Newcastle	Dr. Alex. W. Williamson, F.R.S.	Prof. Liveing, H. L. Pattinson, J. C. Stevenson.
1864. Bath.....	W. Odling, M.D., F.R.S., F.C.S.	A. V. Harcourt, Prof. Liveing, R. Biggs.
1865. Birmingham	Prof. W. A. Miller, M.D., V.P.R.S.	A. V. Harcourt, H. Adkins, Prof. Wanklyn, A. Winkler Wills.
1866. Nottingham	H. Bence Jones, M.D., F.R.S.	J. H. Atherton, Prof. Liveing, W. J. Russell, J. White.
1867. Dundee ...	Prof. T. Anderson, M.D., F.R.S.E.	A. Crum Brown, Prof. G. D. Liveing, W. J. Russell.
1868. Norwich ...	Prof. E. Frankland, F.R.S., F.C.S.	Dr. A. Crum Brown, Dr. W. J. Russell, F. Sutton.
1869. Exeter	Dr. H. Debus, F.R.S., F.C.S.	Prof. A. Crum Brown, Dr. W. J. Russell, Dr. Atkinson.
1870. Liverpool...	Prof. H. E. Roscoe, B.A., F.R.S., F.C.S.	Prof. A. Crum Brown, A. E. Fletcher, Dr. W. J. Russell.
1871. Edinburgh	Prof. T. Andrews, M.D., F.R.S.	J. T. Buchanan, W. N. Hartley, T. E. Thorpe.
1872. Brighton ...	Dr. J. H. Gladstone, F.R.S....	Dr. Mills, W. Chandler Roberts, Dr. W. J. Russell, Dr. T. Wood.
1873. Bradford ...	Prof. W. J. Russell, F.R.S. ...	Dr. Armstrong, Dr. Mills, W. Chandler Roberts, Dr. Thorpe.
1874. Belfast.....	Prof. A. Crum Brown, M.D., F.R.S.E., F.C.S.	Dr. T. Cranstoun Charles, W. Chandler Roberts, Prof. Thorpe.
1875. Bristol	A. G. Vernon Harcourt, M.A., F.R.S., F.C.S.	Dr. H. E. Armstrong, W. Chandler Roberts, W. A. Tilden.
1876. Glasgow ...	W. H. Perkin, F.R.S.	W. Dittmar, W. Chandler Roberts, J. M. Thomson, W. A. Tilden.
1877. Plymouth...	F. A. Abel, F.R.S., F.C.S. ...	Dr. Oxland, W. Chandler Roberts, J. M. Thomson.
1878. Dublin	Prof. Maxwell Simpson, M.D., F.R.S., F.C.S.	W. Chandler Roberts, J. M. Thomson, Dr. C. R. Tichborne, T. Wills.
1879. Sheffield ...	Prof. Dewar, M.A., F.R.S.	H. S. Bell, W. Chandler Roberts, J. M. Thomson.
1880. Swansea ...	Joseph Henry Gilbert, Ph.D., F.R.S.	P. Phillips Bedson, H. B. Dixon, Dr. W. R. Eaton Hodgkinson, J. M. Thomson.
1881. York.....	Prof. A. W. Williamson, Ph.D., F.R.S.	P. Phillips Bedson, H. B. Dixon, T. Gough.
1882. Southampton.	Prof. G. D. Liveing, M.A., F.R.S.	P. Phillips Bedson, H. B. Dixon, J. L. Notter.
1883. Southport	Dr. J. H. Gladstone, F.R.S...	Prof. P. Phillips Bedson, H. B. Dixon, H. Forster Morley.
1884. Montreal ...	Prof. Sir H. E. Roscoe, Ph.D., LL.D., F.R.S.	Prof. P. Phillips Bedson, H. B. Dixon, T. McFarlane, Prof. W. H. Pike.
1885. Aberdeen ...	Prof. H. E. Armstrong, Ph.D., F.R.S., Sec. C.S.	Prof. P. Phillips Bedson, H. B. Dixon, H. Forster Morley, Dr. W. J. Simpson.
1886. Birmingham	W. Crookes, F.R.S., V.P.C.S.	Prof. P. Phillips Bedson, H. B. Dixon, H. Forster Morley, W. W. J. Nicol, C. J. Woodward.
1887. Manchester	Dr. E. Schunck, F.R.S., F.C.S.	Prof. P. Phillips Bedson, H. Forster Morley, W. Thomson.
1888. Bath.....	Prof. W. A. Tilden, D.Sc., F.R.S., V.P.C.S.	Prof. H. B. Dixon, Dr. H. Forster Morley, R. E. Moyle, Dr. W. W. J. Nicol.

Date and Place	Presidents	Secretaries
GEOLOGICAL (AND, UNTIL 1851, GEOGRAPHICAL) SCIENCE.		
COMMITTEE OF SCIENCES, III.—GEOLOGY AND GEOGRAPHY.		
1832. Oxford	R. I. Murchison, F.R.S.	John Taylor.
1833. Cambridge.	G. B. Greenough, F.R.S.	W. Lonsdale, John Phillips.
1834. Edinburgh.	Prof. Jameson	Prof. Phillips, T. Jameson Torrie, Rev. J. Yates.

SECTION C.—GEOLOGY AND GEOGRAPHY.

1835. Dublin	R. J. Griffith	Captain Portlock, T. J. Torrie.
1836. Bristol	Rev. Dr. Buckland, F.R.S.— <i>Geography</i> , R. I. Murchison, F.R.S.	William Sanders, S. Stutchbury, T. J. Torrie.
1837. Liverpool...	Rev. Prof. Sedgwick, F.R.S.— <i>Geography</i> , G. B. Greenough, F.R.S.	Captain Portlock, R. Hunter.— <i>Geo-</i> <i>graphy</i> , Captain H. M. Denham, R.N.
1838. Newcastle..	C. Lyell, F.R.S., V.P.G.S.— <i>Geography</i> , Lord Prudhope.	W. C. Trevelyan, Capt. Portlock.— <i>Geography</i> , Capt. Washington.
1839. Birmingham	Rev. Dr. Buckland, F.R.S.— <i>Geography</i> , G. B. Greenough, F.R.S.	George Lloyd, M.D., H. E. Strick- land, Charles Darwin.
1840. Glasgow ...	Charles Lyell, F.R.S.— <i>Geo-</i> <i>graphy</i> , G. B. Greenough, F.R.S.	W. J. Hamilton, D. Milne, Hugh Murray, H. E. Strickland, John Scouler, M.D.
1841. Plymouth...	H. T. De la Beche, F.R.S. ...	W. J. Hamilton, Edward Moore, M.D., R. Hutton.
1842. Manchester	R. I. Murchison, F.R.S.	E. W. Binney, R. Hutton, Dr. R. Lloyd, H. E. Strickland.
1843. Cork	Richard E. Griffith, F.R.S., M.R.I.A.	Francis M. Jennings, H. E. Strick- land.
1844. York	Henry Warburton, M.P., Pres. Geol. Soc.	Prof. Ansted, E. H. Bunbury.
1845. Cambridge.	Rev. Prof. Sedgwick, M.A., F.R.S.	Rev. J. C. Cumming, A. C. Ramsay, Rev. W. Thorp.
1846. Southamp- ton.	Leonard Horner, F.R.S.— <i>Geo-</i> <i>graphy</i> , G. B. Greenough, F.R.S.	Robert A. Austen, Dr. J. H. Norton, Prof. Oldham.— <i>Geography</i> , Dr. C. T. Beke.
1847. Oxford.....	Very Rev. Dr. Buckland, F.R.S.	Prof. Ansted, Prof. Oldham, A. C. Ramsay, J. Ruskin.
1848. Swansea ...	Sir H. T. De la Beche, C.B., F.R.S.	Starling Benson, Prof. Oldham, Prof. Ramsay.
1849. Birmingham	Sir Charles Lyell, F.R.S., F.G.S.	J. Beete Jukes, Prof. Oldham, Prof. A. C. Ramsay.
1850. Edinburgh ¹	Sir Roderick I. Murchison, F.R.S.	A. Keith Johnston, Hugh Miller, Prof. Nicol.

SECTION C (continued).—GEOLOGY.

1851. Ipswich ...	William Hopkins, M.A., F.R.S.	C. J. F. Bunbury, G. W. Ormerod, Searles Wood.
1852. Belfast.....	Lieut.-Col. Portlock, R.E., F.R.S.	James Bryce, James MacAdam, Prof. M'Coy, Prof. Nicol.

¹ At a meeting of the General Committee held in 1850, it was resolved 'That the subject of Geography be separated from Geology and combined with Ethnology, to constitute a separate Section, under the title of the "Geographical and Ethnological Section,"' for Presidents and Secretaries of which see page liv.

Date and Place	Presidents	Secretaries
1853. Hull	Prof. Sedgwick, F.R.S.....	Prof. Harkness, William Lawton.
1854. Liverpool..	Prof. Edward Forbes, F.R.S.	John Cunningham, Prof. Harkness, G. W. Ormerod, J. W. Woodall.
1855. Glasgow ...	Sir R. I. Murchison, F.R.S....	James Bryce, Prof. Harkness, Prof. Nicol.
1856. Cheltenham	Prof. A. C. Ramsay, F.R.S....	Rev. P. B. Brodie, Rev. R. Hep- worth, Edward Hull, J. Scougall, T. Wright.
1857. Dublin	The Lord Talbot de Malahide	Prof. Harkness, Gilbert Sanders, • Robert H. Scott.
1858. Leeds	William Hopkins, M.A., LL.D., F.R.S.	Prof. Nicol, H. C. Sorby, E. W. Shaw.
1859. Aberdeen...	Sir Charles Lyell, LL.D., D.C.L., F.R.S.	Prof. Harkness, Rev. J. Longmuir, H. C. Sorby.
1860. Oxford	Rev. Prof. Sedgwick, LL.D., F.R.S., F.G.S.	Prof. Harkness, Edward Hull, Capt. D. C. L. Woodall.
1861. Manchester	Sir R. I. Murchison, D.C.L., LL.D., F.R.S.	Prof. Harkness, Edward Hull, T. Rupert Jones, G. W. Ormerod.
1862. Cambridge	J. Beete Jukes, M.A., F.R.S.	Lucas Barrett, Prof. T. Rupert Jones, H. C. Sorby.
1863. Newcastle	Prof. Warrington W. Smyth, F.R.S., F.G.S.	E. F. Boyd, John Daglish, H. C. Sorby, Thomas Sopwith.
1864. Bath.....	Prof. J. Phillips, LL.D., F.R.S., F.G.S.	W. B. Dawkins, J. Johnston, H. C. Sorby, W. Pengelly.
1865. Birmingham	Sir R. I. Murchison, Bart., K.C.B.	Rev. P. B. Brodie, J. Jones, Rev. E. Myers, H. C. Sorby, W. Pengelly.
1866. Nottingham	Prof. A. C. Ramsay, LL.D., F.R.S.	R. Etheridge, W. Pengelly, T. Wil- son, G. H. Wright.
1867. Dundee ...	Archibald Geikie, F.R.S., F.G.S.	Edward Hull, W. Pengelly, Henry Woodward.
1868. Norwich ...	R. A. C. Godwin-Austen, F.R.S., F.G.S.	Rev. O. Fisher, Rev. J. Gunn, W. Pengelly, Rev. H. H. Winwood.
1869. Exeter	Prof. R. Harkness, F.R.S., F.G.S.	W. Pengelly, W. Boyd Dawkins, Rev. H. H. Winwood.
1870. Liverpool...	Sir Philip de M. Grey Egerton, Bart., M.P., F.R.S.	W. Pengelly, Rev. H. H. Winwood, W. Boyd Dawkins, G. H. Morton.
1871. Edinburgh	Prof. A. Geikie, F.R.S., F.G.S.	R. Etheridge, J. Geikie, T. McKenny Hughes, L. C. Miall.
1872. Brighton ...	R. A. C. Godwin-Austen, F.R.S., F.G.S.	L. C. Miall, George Scott, William Topley, Henry Woodward.
1873. Bradford ...	Prof. J. Phillips, D.C.L., F.R.S., F.G.S.	L. C. Miall, R. H. Tiddeman, W. Topley.
1874. Belfast.....	Prof. Hull, M.A., F.R.S., F.G.S.	F. Drew, L. C. Miall, R. G. Symes, R. H. Tiddeman.
1875. Bristol	Dr. Thomas Wright, F.R.S.E., F.G.S.	L. C. Miall, E. B. Tawney, W. Top- ley.
1876. Glasgow ...	Prof. John Young, M.D.	J. Armstrong, F. W. Rudler, W. Topley.
1877. Plymouth...	W. Pengelly, F.R.S.....	Dr. Le Neve Foster, R. H. Tidde- man, W. Topley.
1878. Dublin.....	John Evans, D.C.L., F.R.S., F.S.A., F.G.S.	E. T. Hardman, Prof. J. O'Reilly, R. H. Tiddeman.
1879. Sheffield ...	Prof. P. Martin Duncan, M.B., F.R.S., F.G.S.	W. Topley, G. Blake Walker.
1880. Swansea ...	H. C. Sorby, LL.D., F.R.S., F.G.S.	W. Topley, W. Whitaker.
1881. York.....	A. C. Ramsay, LL.D., F.R.S., F.G.S.	J. E. Clark, W. Keeping, W. Topley, W. Whitaker.
1882. Southamp- ton.	R. Etheridge, F.R.S., F.G.S.	T. W. Shore, W. Topley, E. West- lake, W. Whitaker.

1888.

Date and Place	Presidents	Secretaries
1883. Southport	Prof. W. C. Williamson, LL.D., F.R.S.	R. Betley, C. E. De Rance, W. Topley, W. Whitaker.
1884. Montreal ...	W. T. Blanford, F.R.S., Sec. G.S.	F. Adams, Prof. E. W. Claypole, W. Topley, W. Whitaker.
1885. Aberdeen ...	Prof. J. W. Judd, F.R.S., Sec. G.S.	C. E. De Rance, J. J. H. Teall, W. Topley.
1886. Birmingham	Prof. T. G. Bonney, D.Sc., LL.D., F.R.S., F.G.S.	W. J. Harrison, J. J. H. Teall, W. Topley, W. W. Watts.
1887. Manchester	Henry Woodward, LL.D., F.R.S., F.G.S.	J. E. Marr, J. J. H. Teall, W. Topley, W. W. Watts.
1888. Bath.....	Prof. W. Boyd Dawkins, M.A., F.R.S., F.G.S.	Prof. G. A. Lebour, W. Topley, W. W. Watts, H. B. Woodward.

BIOLOGICAL SCIENCES.

COMMITTEE OF SCIENCES, IV.—ZOOLOGY, BOTANY, PHYSIOLOGY, ANATOMY.

1832. Oxford.....	Rev. P. B. Duncan, F.G.S. ...	Rev. Prof. J. S. Henslow.
1833. Cambridge ¹	Rev. W. L. P. Garnons, F.L.S.	C. C. Babington, D. Don.
1834. Edinburgh.	Prof. Graham.....	W. Yarrell, Prof. Burnett.

SECTION D.—ZOOLOGY AND BOTANY.

1835. Dublin.....	Dr. Allman.....	J. Curtis, Dr. Litton.
1836. Bristol.....	Rev. Prof. Henslow	J. Curtis, Prof. Don, Dr. Riley, S. Rootsey.
1837. Liverpool...	W. S. MacLeay.....	C. C. Babington, Rev. L. Jenyns, W. Swainson.
1838. Newcastle	Sir W. Jardine, Bart.	J. E. Gray, Prof. Jones, R. Owen, Dr. Richardson.
1839. Birmingham	Prof. Owen, F.R.S.	E. Forbes, W. Ick, R. Patterson.
1840. Glasgow ...	Sir W. J. Hooker, LL.D.....	Prof. W. Couper, E. Forbes, R. Patterson.
1841. Plymouth...	John Richardson, M.D., F.R.S.	J. Couch, Dr. Lankester, R. Patterson.
1842. Manchester	Hon. and Very Rev. W. Herbert, LL.D., F.L.S.	Dr. Lankester, R. Patterson, J. A. Turner.
1843. Cork.....	William Thompson, F.L.S. ...	G. J. Allman, Dr. Lankester, R. Patterson.
1844. York.....	Very Rev. the Dean of Manchester.	Prof. Allman, H. Goodsir, Dr. King, Dr. Lankester.
1845. Cambridge	Rev. Prof. Henslow, F.L.S....	Dr. Lankester, T. V. Wollaston.
1846. Southampton.	Sir J. Richardson, M.D., F.R.S.	Dr. Lankester, T. V. Wollaston, H. Wooldridge.
1847. Oxford.....	H. E. Strickland, M.A., F.R.S.	Dr. Lankester, Dr. Melville, T. V. Wollaston.

SECTION D (*continued*).—ZOOLOGY AND BOTANY, INCLUDING PHYSIOLOGY.

[For the Presidents and Secretaries of the Anatomical and Physiological Subsections and the temporary Section E of Anatomy and Medicine, see p. liii.]

1848. Swansea ...	L. W. Dillwyn, F.R.S.....	Dr. R. Wilbraham Falconer, A. Henfrey, Dr. Lankester.
1849. Birmingham	William Spence, F.R.S.	Dr. Lankester, Dr. Russell.
1850. Edinburgh	Prof. Goodsir, F.R.S. L. & E.	Prof. J. H. Bennett, M.D., Dr. Lankester, Dr. Douglas MacLagan.

¹ At this Meeting Physiology and Anatomy were made a separate Committee, for Presidents and Secretaries of which see p. liii.

Date and Place	Presidents	Secretaries
1851. Ipswich ...	Rev. Prof. Henslow, M.A., F.R.S.	Prof. Allman, F. W. Johnston, Dr. E. Lankester.
1852. Belfast.....	W. Ogilby	Dr. Dickie, George C. Hyndman, Dr. Edwin Lankester.
1853. Hull.....	C. C. Babington, M.A., F.R.S.	Robert Harrison, Dr. E. Lankester.
1854. Liverpool...	Prof. Balfour, M.D., F.R.S....	Isaac Byerley, Dr. E. Lankester.
1855. Glasgow ...	Rev. Dr. Fleeming, F.R.S.E.	William Keddie, Dr. Lankester.
1856. Cheltenham	Thomas Bell, F.R.S., Pres.L.S.	Dr. J. Abercrombie, Prof. Buckman, Dr. Lankester.
1857. Dublin.....	Prof. W. H. Harvey, M.D., F.R.S.	Prof. J. R. Kinahan, Dr. E. Lankester, Robert Patterson, Dr. W. E. Steele.
1858. Leeds	C. C. Babington, M.A., F.R.S.	Henry Denny, Dr. Heaton, Dr. E. Lankester, Dr. E. Perceval Wright.
1859. Aberdeen...	Sir W. Jardine, Bart., F.R.S.E.	Prof. Dickie, M.D., Dr. E. Lankester, Dr. Ogilvy.
1860. Oxford.....	Rev. Prof. Henslow, F.L.S....	W. S. Church, Dr. E. Lankester, P. L. Sclater, Dr. E. Perceval Wright.
1861. Manchester	Prof. C. C. Babington, F.R.S.	Dr. T. Alcock, Dr. E. Lankester, Dr. P. L. Sclater, Dr. E. P. Wright.
1862. Cambridge	Prof. Huxley, F.R.S.	Alfred Newton, Dr. E. P. Wright.
1863. Newcastle	Prof. Balfour, M.D., F.R.S....	Dr. E. Charlton, A. Newton, Rev. H. B. Tristram, Dr. E. P. Wright.
1864. Bath.....	Dr. John E. Gray, F.R.S. ...	H. B. Brady, C. E. Brooth, H. T. Stainton, Dr. E. P. Wright.
1865. Birmingham	T. Thomson, M.D., F.R.S. ...	Dr. J. Anthony, Rev. C. Clarke, Rev. H. B. Tristram, Dr. E. P. Wright.

SECTION D (*continued*).—BIOLOGY.¹

1866. Nottingham	Prof. Huxley, LL.D., F.R.S.— <i>Physiological Dep.</i> , Prof. Humphry, M.D., F.R.S.— <i>Anthropological Dep.</i> , Alf. R. Wallace, F.R.G.S.	Dr. J. Beddard, W. Felkin, Rev. H. B. Tristram, W. Turner, E. B. Tylor, Dr. E. P. Wright.
1867. Dundee ...	Prof. Sharpey, M.D., Sec. R.S.— <i>Dep. of Zool. and Bot.</i> , George Busk, M.D., F.R.S.	C. Spence Bate, Dr. S. Cobbold, Dr. M. Foster, H. T. Stainton, Rev. H. B. Tristram, Prof. W. Turner.
1868. Norwich ...	Rev. M. J. Berkeley, F.L.S.— <i>Dep. of Physiology</i> , W. H. Flower, F.R.S.	Dr. T. S. Cobbold, G. W. Firth, Dr. M. Foster, Prof. Lawson, H. T. Stainton, Rev. Dr. H. B. Tristram, Dr. E. P. Wright.
1869. Exeter	George Busk, F.R.S., F.L.S.— <i>Dep. of Bot. and Zool.</i> , C. Spence Bate, F.R.S.— <i>Dep. of Ethno.</i> , E. B. Tylor.	Dr. T. S. Cobbold, Prof. M. Foster, E. Ray Lankester, Prof. Lawson, H. T. Stainton, Rev. H. B. Tristram.
1870. Liverpool...	Prof. G. Rolleston, M.A., M.D., F.R.S., F.L.S.— <i>Dep. of Anat. and Physiol.</i> , Prof. M. Foster, M.D., F.L.S.— <i>Dep. of Ethno.</i> , J. Evans, F.R.S.	Dr. T. S. Cobbold, Sebastian Evans, Prof. Lawson, Thos. J. Moore, H. T. Stainton, Rev. H. B. Tristram, C. Staniland Wake, E. Ray Lankester.
1871. Edinburgh.	Prof. Allen Thomson, M.D., F.R.S.— <i>Dep. of Bot. and Zool.</i> , Prof. Wyville Thomson, F.R.S.— <i>Dep. of Anthropol.</i> , Prof. W. Turner, M.D.	Dr. T. R. Fraser, Dr. Arthur Gamgee, E. Ray Lankester, Prof. Lawson, H. T. Stainton, C. Staniland Wake, Dr. W. Rutherford, Dr. Kelburne King.

¹ At a meeting of the General Committee in 1865, it was resolved:—‘That the title of Section D be changed to Biology;’ and ‘That for the word “Subsection,” in the rules for conducting the business of the Sections, the word “Department” be substituted.’

Date and Place	Presidents	Secretaries
1872. Brighton ...	Sir J. Lubbock, Bart., F.R.S.— <i>Dep. of Anat. and Physiol.</i> , Dr. Burdon Sanderson, F.R.S.— <i>Dep. of Anthropol.</i> , Col. A. Lane Fox, F.G.S.	Prof. Thiselton-Dyer, H. T. Stainton, Prof. Lawson, F. W. Rudler, J. H. Lamprey, Dr. Gamgee, E. Ray Lankester, Dr. Pye-Smith.
1873. Bradford ...	Prof. Allman, F.R.S.— <i>Dep. of</i> <i>Anat. and Physiol.</i> , Prof. Ru- therford, M.D.— <i>Dep. of An-</i> <i>thropol.</i> , Dr. Beddoe, F.R.S.	Prof. Thiselton-Dyer, Prof. Lawson, R. M'Lachlan, Dr. Pye-Smith, E. Ray Lankester, F. W. Rudler, J. H. Lamprey.
1874. Belfast	Prof. Redfern, M.D.— <i>Dep. of</i> <i>Zool. and Bot.</i> , Dr. Hooker, C.B., Pres. R.S.— <i>Dep. of An-</i> <i>thropol.</i> , Sir W. R. Wilde, M.D.	W. T. Thiselton-Dyer, R. O. Cunning- ham, Dr. J. J. Charles, Dr. P. H. Pye-Smith, J. J. Murphy, F. W. Rudler.
1875. Bristol	P. L. Sclater, F.R.S.— <i>Dep. of</i> <i>Anat. and Physiol.</i> , Prof. Cle- land, M.D., F.R.S.— <i>Dep. of</i> <i>Anthropol.</i> , Prof. Rolleston, M.D., F.R.S.	E. R. Alston, Dr. McKendrick, Prof. W. R. M'Nab, Dr. Martyn, F. W. Rudler, Dr. P. H. Pye-Smith, Dr. W. Spencer.
1876. Glasgow ...	A. Russel Wallace, F.R.G.S., F.L.S.— <i>Dep. of Zool. and</i> <i>Bot.</i> , Prof. A. Newton, M.A., F.R.S.— <i>Dep. of Anat. and</i> <i>Physiol.</i> , Dr. J. G. McKen- drick, F.R.S.E.	E. R. Alston, Hyde Clarke, Dr. Knox, Prof. W. R. M'Nab, Dr. Muirhead, Prof. Morrison Wat- son.
1877. Plymouth...	J. Gwyn Jeffreys, LL.D., F.R.S., F.L.S.— <i>Dep. of Anat. and</i> <i>Physiol.</i> , Prof. Macalister, M.D.— <i>Dep. of Anthropol.</i> , Francis Galton, M.A., F.R.S.	E. R. Alston, F. Brent, Dr. D. J. Cunningham, Dr. C. A. Hingston, Prof. W. R. M'Nab, J. B. Rowe, F. W. Rudler.
1878. Dublin	Prof. W. H. Flower, F.R.S.— <i>Dep. of Anthropol.</i> , Prof. Huxley, Sec. R.S.— <i>Dep.</i> <i>of Anat. and Physiol.</i> , R. McDonnell, M.D., F.R.S.	Dr. R. J. Harvey, Dr. T. Hayden, Prof. W. R. M'Nab, Prof. J. M. Purser, J. B. Rowe, F. W. Rudler.
1879. Sheffield ...	Prof. St. George Mivart, F.R.S.— <i>Dep. of Anthropol.</i> , E. B. Tylor, D.C.L., F.R.S. — <i>Dep. of Anat. and Phy-</i> <i>siol.</i> , Dr. Pye-Smith.	Arthur Jackson, Prof. W. R. M'Nab, J. B. Rowe, F. W. Rudler, Prof. Schäfer.
1880. Swansea ...	A. C. L. Günther, M.D., F.R.S. — <i>Dep. of Anat. and Phy-</i> <i>siol.</i> , F. M. Balfour, M.A., F.R.S.— <i>Dep. of Anthropol.</i> , F. W. Rudler, F.G.S.	G. W. Bloxam, John Priestley, Howard Saunders, Adam Sedg- wick.
1881. York	Richard Owen, C.B., M.D., F.R.S.— <i>Dep. of Anthropol.</i> , Prof. W. H. Flower, LL.D., F.R.S.— <i>Dep. of Anat. and</i> <i>Physiol.</i> , Prof. J. S. Burdon Sanderson, M.D., F.R.S.	G. W. Bloxam, W. A. Forbes, Rev. W. C. Hey, Prof. W. R. M'Nab, W. North, John Priestley, Howard Saunders, H. E. Spencer.
1882. Southamp- ton.	Prof. A. Gamgee, M.D., F.R.S. — <i>Dep. of Zool. and Bot.</i> , Prof. M. A. Lawson, M.A., F.L.S.— <i>Dep. of Anthropol.</i> , Prof. W. Boyd Dawkins, M.A., F.R.S.	G. W. Bloxam, W. Heape, J. B. Nias, Howard Saunders, A. Sedg- wick, T. W. Shore, jun.

Date and Place	Presidents	Secretaries
1883. Southport ¹	Prof. E. Ray Lankester, M.A., F.R.S.— <i>Dep. of Anthropol.</i> , W. Pengelly, F.R.S.	G. W. Bloxam, Dr. G. J. Haslam, W. Heape, W. Hurst, Prof. A. M. Marshall, Howard Saunders, Dr. G. A. Woods.
1884. Montreal ²	Prof. H. N. Moseley, M.A., F.R.S.	Prof. W. Osler, Howard Saunders, A. Sedgwick, Prof. R. R. Wright.
1885. Aberdeen ...	Prof. W. C. McIntosh, M.D., LL.D., F.R.S. L. & E.	W. Heape, J. McGregor-Robertson, J. Duncan Matthews, Howard Saunders, H. Marshall Ward.
1886. Birmingham	W. Carruthers, Pres. L.S., F.R.S., F.G.S.	Prof. T. W. Bridge, W. Heape, Prof. W. Hillhouse, W. L. Sclater, Prof. H. Marshall Ward.
1887. Manchester	Prof. A. Newton, M.A., F.R.S., F.L.S., V.P.Z.S.	C. Bailey, F. E. Beddard, S. F. Har- mer, W. Heape, W. L. Sclater, Prof. H. Marshall Ward.
1888. Bath	W. T. Thiselton-Dyer, C.M.G., F.R.S., F.L.S.	F. E. Beddard, S. F. Harmer, Prof. H. Marshall Ward, W. Gardiner, Prof. W. D. Halliburton.

ANATOMICAL AND PHYSIOLOGICAL SCIENCES.

COMMITTEE OF SCIENCES, V.—ANATOMY AND PHYSIOLOGY.

1833. Cambridge	Dr. Haviland	Dr. Bond, Mr. Paget.
1834. Edinburgh	Dr. Abercrombie	Dr. Roget, Dr. William Thomson.

SECTION E (UNTIL 1847).—ANATOMY AND MEDICINE.

1835. Dublin	Dr. Pritchard	Dr. Harrison, Dr. Hart.
1836. Bristol	Dr. Roget, F.R.S.	Dr. Symonds.
1837. Liverpool...	Prof. W. Clark, M.D.	Dr. J. Carson, jun., James Long, Dr. J. R. W. Vose.
1838. Newcastle	T. E. Headlam, M.D.	T. M. Greenhow, Dr. J. R. W. Vose.
1839. Birmingham	John Yelloly, M.D., F.R.S....	Dr. G. O. Rees, F. Ryland.
1840. Glasgow ...	James Watson, M.D.	Dr. J. Brown, Prof. Couper, Prof. Reid.

SECTION E.—PHYSIOLOGY.

1841. Plymouth...	P. M. Roget, M.D., Sec. R.S.	Dr. J. Butter, J. Fuge, Dr. R. S. Sargent.
1842. Manchester	Edward Holme, M.D., F.L.S.	Dr. Chaytor, Dr. R. S. Sargent.
1843. Cork	Sir James Pitcairn, M.D. ...	Dr. John Popham, Dr. R. S. Sargent.
1844. York	J. C. Pritchard, M.D.	I. Erichsen, Dr. R. S. Sargent.
1845. Cambridge	Prof. J. Haviland, M.D.	Dr. R. S. Sargent, Dr. Webster.
1846. Southamp- ton.	Prof. Owen, M.D., F.R.S. ...	C. P. Keele, Dr. Laycock, Dr. Sar- gent.
1847. Oxford ³ ...	Prof. Ogle, M.D., F.R.S.	Dr. Thomas K. Chambers, W. P. Ormerod.

¹ By direction of the General Committee at Southampton (1882) the Departments of Zoology and Botany and of Anatomy and Physiology were amalgamated.

² By authority of the General Committee, Anthropology was made a separate Section, for Presidents and Secretaries of which see p. lix.

³ By direction of the General Committee at Oxford, Sections D and E were incorporated under the name of 'Section D—Zoology and Botany, including Physiology' (see p. l). The Section being then vacant was assigned in 1851 to Geography.

Date and Place	Presidents	Secretaries
PHYSIOLOGICAL SUBSECTIONS OF SECTION D.		
1850. Edinburgh	Prof. Bennett, M.D., F.R.S.E.	
1855. Glasgow ...	Prof. Allen Thomson, F.R.S.	Prof. J. H. Corbett, Dr. J. Struthers.
1857. Dublin.....	Prof. R. Harrison, M.D.	Dr. R. D. Lyons, Prof. Redfern.
1858. Leeds	Sir Benjamin Brodie, Bart., F.R.S.	C. G. Wheelhouse.
1859. Aberdeen...	Prof. Sharpey, M.D., Sec.R.S.	Prof. Bennett, Prof. Redfern.
1860. Oxford.....	Prof. G. Rolleston, M.D., F.L.S.	Dr. R. M'Donnell, Dr. Edward Smith.
1861. Manchester	Dr. John Davy, F.R.S.L. & E.	Dr. W. Roberts, Dr. Edward Smith.
1862. Cambridge	G. E. Paget, M.D.....	G. F. Helm, Dr. Edward Smith.
1863. Newcastle	Prof. Rolleston, M.D., F.R.S.	Dr. D. Embleton, Dr. W. Turner.
1864. Bath.....	Dr. Edward Smith, LL.D., F.R.S.	J. S. Bartrum, Dr. W. Turner.
1865. Birming- ham. ¹	Prof. Acland, M.D., LL.D., F.R.S.	Dr. A. Fleming, Dr. P. Hcslop, Oliver Pembleton, Dr. W. Turner.

GEOGRAPHICAL AND ETHNOLOGICAL SCIENCES.

[For Presidents and Secretaries for Geography previous to 1851, see Section C. p. xlviii.]

ETHNOLOGICAL SUBSECTIONS OF SECTION D.

1846. Southampton	Dr. Pritchard.....	Dr. King.
1847. Oxford	Prof. H. H. Wilson, M.A. ...	Prof. Buckley.
1848. Swansea	G. Grant Francis.
1849. Birmingham	Dr. R. G. Latham.
1850. Edinburgh	Vice-Admiral Sir A. Malcolm	Daniel Wilson.

SECTION E.—GEOGRAPHY AND ETHNOLOGY.

1851. Ipswich ...	Sir R. I. Murchison, F.R.S., Pres. R.G.S.	R. Cull, Rev. J. W. Donaldson, Dr. Norton Shaw.
1852. Belfast.....	Col. Chesney, R.A., D.C.L., F.R.S.	R. Cull, R. MacAdam, Dr. Norton Shaw.
1853. Hull	R. G. Latham, M.D., F.R.S.	R. Cull, Rev. H. W. Kemp, Dr. Norton Shaw.
1854. Liverpool...	Sir R. I. Murchison, D.C.L., F.R.S.	Richard Cull, Rev. H. Higgins, Dr. Ihne, Dr. Norton Shaw.
1855. Glasgow ...	Sir J. Richardson, M.D., F.R.S.	Dr. W. G. Blackie, R. Cull, Dr. Norton Shaw.
1856. Cheltenham	Col. Sir H. C. Rawlinson, K.C.B.	R. Cull, F. D. Hartland, W. H. Rumsey, Dr. Norton Shaw.
1857. Dublin.....	Rev. Dr. J. Henthorn Todd, Pres. R.I.A.	R. Cull, S. Ferguson, Dr. R. R. Madden, Dr. Norton Shaw.
1858, Leeds	Sir R. I. Murchison, G.C.St.S., F.R.S.	R. Cull, Francis Galton, P. O'Cal- laghan, Dr. Norton Shaw, Thomas Wright.
1859. Aberdeen...	Rear - Admiral Sir James Clerk Ross, D.C.L., F.R.S.	Richard Cull, Prof. Geddes, Dr. Nor- ton Shaw.
1860. Oxford.....	Sir R. I. Murchison, D.C.L., F.R.S.	Capt. Burrows, Dr. J. Hunt, Dr. C. Lemprière, Dr. Norton Shaw.
1861. Manchester	John Crawford, F.R.S.....	Dr. J. Hunt, J. Kingsley, Dr. Nor- ton Shaw, W. Spottiswoode.
1862. Cambridge	Francis Galton, F.R.S.....	J. W. Clarke, Rev. J. Glover, Dr. Hunt, Dr. Norton Shaw, T. Wright.

Vide note on page xlviii.

Date and Place	Presidents	Secretaries
1863. Newcastle	Sir R. I. Murchison, K.C.B., F.R.S.	C. Carter Blake, Hume Greenfield, C. R. Markham, R. S. Watson.
1864. Bath.....	Sir R. I. Murchison, K.C.B., F.R.S.	H. W. Bates, C. R. Markham, Capt. R. M. Murchison, T. Wright.
1865. Birmingham	Major-General Sir H. Raw- linson, M.P., K.C.B., F.R.S.	H. W. Bates, S. Evans, G. Jabet, C. R. Markham, Thomas Wright.
1866. Nottingham	Sir Charles Nicholson, Bart., LL.D.	H. W. Bates, Rev. E. T. Cusins, R. H. Major, Clements R. Markham, D. W. Nash, T. Wright.
1867. Dundee ...	Sir Samuel Baker, F.R.G.S.	H. W. Bates, Cyril Graham, Clements R. Markham, S. J. Mackie, R. Sturrock.
1868. Norwich ...	Capt. G. H. Richards, R.N., F.R.S.	T. Baines, H. W. Bates, Clements R. Markham, T. Wright.

SECTION E (*continued*).—GEOGRAPHY.

1869. Exeter	Sir Bartle Frere, K.C.B., LL.D., F.R.G.S.	H. W. Bates, Clements R. Markham J. H. Thomas.
1870. Liverpool...	Sir R. I. Murchison, Bt., K.C.B., LL.D., D.C.L., F.R.S., F.G.S.	H. W. Bates, David Buxton, Albert J. Mott, Clements R. Markham.
1871. Edinburgh	Colonel Yule, C.B., F.R.G.S.	A. Buchan, A. Keith Johnston, Cle- ments R. Markham, J. H. Thomas.
1872. Brighton ...	Francis Galton, F.R.S.....	H. W. Bates, A. Keith Johnston, Rev. J. Newton, J. H. Thomas.
1873. Bradford...	Sir Rutherford Alcock, K.C.B.	H. W. Bates, A. Keith Johnston, Clements R. Markham.
1874. Belfast.....	Major Wilson, R.E., F.R.S., F.R.G.S.	E. G. Ravenstein, E. C. Rye, J. H. Thomas.
1875. Bristol	Lieut. - General Strachey, R.E., C.S.I., F.R.S., F.R.G.S., F.L.S., F.G.S.	H. W. Bates, E. C. Rye, F. F. Tuckett.
1876. Glasgow ...	Capt. Evans, C.B., F.R.S.....	H. W. Bates, E. C. Rye, R. Oliphant Wood.
1877. Plymouth...	Adm. Sir E. Ommanney, C.B., F.R.S., F.R.G.S., F.R.A.S.	H. W. Bates, F. E. Fox, E. C. Rye.
1878. Dublin	Prof. Sir C. Wyville Thom- son, LL.D., F.R.S.L.&E.	John Coles, E. C. Rye.
1879. Sheffield ...	Clements R. Markham, C.B., F.R.S., Sec. R.G.S.	H. W. Bates, C. E. D. Black, E. C. Rye.
1880. Swansea ...	Lieut.-Gen. Sir J. H. Lefroy, C.B., K.C.M.G., R.A., F.R.S., F.R.G.S.	H. W. Bates, E. C. Rye.
1881. York.....	Sir J. D. Hooker, K.C.S.I., C.B., F.R.S.	J. W. Barry, H. W. Bates.
1882. Southamp- ton.	Sir R. Temple, Bart., G.C.S.I., F.R.G.S.	E. G. Ravenstein, E. C. Rye.
1883. Southport	Lieut.-Col. H. H. Godwin- Austen, F.R.S.	John Coles, E. G. Ravenstein, E. C. Rye.
1884. Montreal ...	Gen. Sir J. H. Lefroy, C.B., K.C.M.G., F.R.S., V.P.R.G.S.	Rev. Abbé Laflamme, J. S. O'Halloran, E. G. Ravenstein, J. F. Torrance.
1885. Aberdeen...	Gen. J. T. Walker, C.B., R.E., LL.D., F.R.S.	J. S. Keltie, J. S. O'Halloran, E. G. Ravenstein, Rev. G. A. Smith.
1886. Birmingham	Maj.-Gen. Sir F. J. Goldsmid, K.C.S.I., C.B., F.R.G.S.	F. T. S. Houghton, J. S. Keltie, E. G. Ravenstein.
1887. Manchester	Col. Sir C. Warren, R.E., G.C.M.G., F.R.S., F.R.G.S.	Rev. L. C. Casartelli, J. S. Keltie, H. J. Mackinder, E. G. Raven- stein.
1888. Bath.....	Col. Sir C. W. Wilson, R.E., K.C.B., F.R.S., F.R.G.S.	J. S. Keltie, H. J. Mackinder, E. G. Ravenstein.

STATISTICAL SCIENCE.

COMMITTEE OF SCIENCES, VI.—STATISTICS.

1833. Cambridge	Prof. Babbage, F.R.S.	J. E. Drinkwater.
1834. Edinburgh	Sir Charles Lemon, Bart.....	Dr. Cleland, C. Hope Maclean.

SECTION F.—STATISTICS.

1835. Dublin	Charles Babbage, F.R.S.	W. Greg, Prof. Longfield.
1836. Bristol	Sir Chas. Lemon, Bart., F.R.S.	Rev. J. E. Bromby, C. B. Fripp, James Heywood.
1837. Liverpool...	Rt. Hon. Lord Sandon	W. R. Greg, W. Langton, Dr. W. C. Tayler.
1838. Newcastle	Colonel Sykes, F.R.S.	W. Cargill, J. Heywood, W. R. Wood.
1839. Birmingham	Henry Hallam, F.R.S.	F. Clarke, R. W. Rawson, Dr. W. C. Tayler.
1840. Glasgow ...	Rt. Hon. Lord Sandon, M.P., F.R.S.	C. R. Baird, Prof. Ramsay, R. W. Rawson.
1841. Plymouth...	Lieut.-Col. Sykes, F.R.S.	Rev. Dr. Byrth, Rev. R. Luney, R. W. Rawson.
1842. Manchester	G. W. Wood, M.P., F.L.S. ...	Rev. R. Luney, G. W. Ormerod, Dr. W. C. Tayler.
1843. Cork	Sir C. Lemon, Bart., M.P. ...	Dr. D. Bullen, Dr. W. Cooke Tayler.
1844. York	Lieut. - Col. Sykes, F.R.S., F.L.S.	J. Fletcher, J. Heywood, Dr. Lay- cock.
1845. Cambridge	Rt. Hon. the Earl Fitzwilliam	J. Fletcher, Dr. W. Cooke Tayler.
1846. Southamp- ton.	G. R. Porter, F.R.S.	J. Fletcher, F. G. P. Neison, Dr. W. C. Tayler, Rev. T. L. Shapcott.
1847. Oxford	Travers Twiss, D.C.L., F.R.S.	Rev. W. H. Cox, J. J. Danson, F. G. P. Neison.
1848. Swansea ...	J. H. Vivian, M.P., F.R.S. ...	J. Fletcher, Capt. R. Shortrede.
1849. Birmingham	Rt. Hon. Lord Lyttelton.....	Dr. Finch, Prof. Hancock, F. G. P. Neison.
1850. Edinburgh	Very Rev. Dr. John Lee, V.P.R.S.E.	Prof. Hancock, J. Fletcher, Dr. J. Stark.
1851. Ipswich ...	Sir John P. Boileau, Bart. ...	J. Fletcher, Prof. Hancock.
1852. Belfast.....	His Grace the Archbishop of Dublin.	Prof. Hancock, Prof. Ingram, James MacAdam, jun.
1853. Hull	James Heywood, M.P., F.R.S.	Edward Cheshire, W. Newmarch.
1854. Liverpool...	Thomas Tooke, F.R.S.	E. Cheshire, J. T. Danson, Dr. W. H. Duncan, W. Newmarch.
1855. Glasgow ...	R. Monckton Milnes, M.P. ...	J. A. Campbell, E. Cheshire, W. New- march, Prof. R. H. Walsh.

SECTION F (continued).—ECONOMIC SCIENCE AND STATISTICS.

1856. Cheltenham	Rt. Hon. Lord Stanley, M.P.	Rev. C. H. Bromby, E. Cheshire, Dr. W. N. Hancock, W. Newmarch, W. M. Tartt.
1857. Dublin	His Grace the Archbishop of Dublin, M.R.I.A.	Prof. Cairns, Dr. H. D. Hutton, W. Newmarch.
1858. Leeds	Edward Baines	T. B. Baines, Prof. Cairns, S. Brown, Capt. Fishbourne, Dr. J. Strang.
1859. Aberdeen...	Col. Sykes, M.P., F.R.S.	Prof. Cairns, Edmund Macrory, A. M. Smith, Dr. John Strang.
1860. Oxford	Nassau W. Senior, M.A.	Edmund Macrory, W. Newmarch, Rev. Prof. J. E. T. Rogers.
1861. Manchester	William Newmarch, F.R.S....	David Chadwick, Prof. R. C. Christie, E. Macrory, Rev. Prof. J. E. T. Rogers.

Date and Place	Presidents	Secretaries
1862. Cambridge	Edwin Chadwick, C.B.	H. D. Macleod, Edmund Macrory.
1863. Newcastle	William Tite, M.P., F.R.S. ...	T. Doubleday, Edmund Macrory, Frederick Purdy, James Potts.
1864. Bath	William Farr, M.D., D.C.L., F.R.S.	E. Macrory, E. T. Payne, F. Purdy.
1865. Birmingham	Rt. Hon. Lord Stanley, LL.D., M.P.	G. J. D. Goodman, G. J. Johnston, E. Macrory.
1866. Nottingham	Prof. J. E. T. Rogers.....	R. Birkin, jun., Prof. Leone Levi, E. Macrory.
1867. Dundee	M. E. Grant Duff, M.P.	Prof. Leone Levi, E. Macrory, A. J. Warden.
1868. Norwich ...	Samuel Brown, Pres. Instit. Actuaries.	Rev. W. C. Davie, Prof. Leone Levi.
1869. Exeter	Rt. Hon. Sir Stafford H. North- cote, Bart., C.B., M.P.	E. Macrory, F. Purdy, C. T. D. Acland.
1870. Liverpool...	Prof. W. Stanley Jevons, M.A.	Chas. R. Dudley Baxter, E. Macrory J. Miles Moss.
1871. Edinburgh	Rt. Hon. Lord Neaves	J. G. Fitch, James Meikle.
1872. Brighton ...	Prof. Henry Fawcett, M.P. ...	J. G. Fitch, Barclay Phillips.
1873. Bradford ...	Rt. Hon. W. E. Forster, M.P.	J. G. Fitch, Swire Smith.
1874. Belfast.....	Lord O'Hagan	Prof. Donnell, F. P. Fellows, Hans MacMordie.
1875. Bristol	James Heywood, M.A., F.R.S., Pres.S.S.	F. P. Fellows, T. G. P. Hallett, E. Macrory.
1876. Glasgow ...	Sir George Campbell, K.C.S.I., M.P.	A. M'Neel Caird, T. G. P. Hallett, Dr. W. Neilson Hancock, Dr. W. Jack.
1877. Plymouth...	Rt. Hon. the Earl Fortescue	W. F. Collier, P. Hallett, J. T. Pim.
1878. Dublin	Prof. J. K. Ingram, LL.D., M.R.I.A.	W. J. Hancock, C. Molloy, J. T. Pim.
1879. Sheffield ...	G. Shaw Lefevre, M.P., Pres. S.S.	Prof. Adamson, R. E. Leader, C. Molloy.
1880. Swansea ...	G. W. Hastings, M.P.	N. A. Humphreys, C. Molloy.
1881. York.....	Rt. Hon. M. E. Grant-Duff, M.A., F.R.S.	C. Molloy, W. W. Morrell, J. F. Moss.
1882. Southamp- ton.	Rt. Hon. G. Sclater-Booth, M.P., F.R.S.	G. Baden-Powell, Prof. H. S. Fox- well, A. Milnes, C. Molloy.
1883. Southport	R. H. Inglis Palgrave, F.R.S.	Rev. W. Cunningham, Prof. H. S. Foxwell, J. N. Keynes, C. Molloy.
1884. Montreal ...	Sir Richard Temple, Bart., G.C.S.I., C.I.E., F.R.G.S.	Prof. H. S. Foxwell, J. S. McLennan, Prof. J. Watson.
1885. Aberdeen...	Prof. H. Sidgwick, LL.D., Litt.D.	Rev. W. Cunningham, Prof. H. S. Foxwell, C. McCombie, J. F. Moss.
1886. Birmingham	J. B. Martin, M.A., F.S.S.	F. F. Barham, Rev. W. Cunningham, Prof. H. S. Foxwell, J. F. Moss.
1887. Manchester	Robert Giffen, LL.D., V.P.S.S.	Rev. W. Cunningham, F. Y. Edge- worth, T. H. Elliott, C. Hughes, Prof. J. E. C. Munro, G. H. Sar- gant.
1888. Bath	Rt. Hon. Lord Bramwell, LL.D., F.R.S.	Prof. F. Y. Edgeworth, T. H. Elliott, Prof. H. S. Foxwell, L. L. F. R. Price.

MECHANICAL SCIENCE.

SECTION G.—MECHANICAL SCIENCE.

1886. Bristol	Davies Gilbert, D.C.L., F.R.S.	T. G. Bunt, G. T. Clark, W. West.
1887. Liverpool...	Rev. Dr. Robinson	Charles Vignoles, Thomas Webster.
1888. Newcastle	Charles Babbage, F.R.S.	R. Hawthorn, C. Vignoles, T. Webster.

Date and Place	Presidents	Secretaries
1839. Birmingham	Prof. Willis, F.R.S., and Robt. Stephenson.	W. Carpmael, William Hawkes, T. Webster.
1840. Glasgow	Sir John Robinson	J. Scott Russell, J. Thomson, J. Tod, C. Vignoles.
1841. Plymouth	John Taylor, F.R.S.	Henry Chatfield, Thomas Webster.
1842. Manchester	Rev. Prof. Willis, F.R.S.	J. F. Bateman, J. Scott Russell, J. Thomson, Charles Vignoles.
1843. Cork	Prof. J. Macneill, M.R.I.A. ...	James Thomson, Robert Mallet.
1844. York	John Taylor, F.R.S.	Charles Vignoles, Thomas Webster.
1845. Cambridge	George Rennie, F.R.S.	Rev. W. T. Kingsley.
1846. Southamp- ton.	Rev. Prof. Willis, M.A., F.R.S.	William Betts, jun., Charles Manby.
1847. Oxford	Rev. Prof. Walker, M.A., F.R.S.	J. Glynn, R. A. Le Mesurier.
1848. Swansea ...	Rev. Prof. Walker, M.A., F.R.S.	R. A. Le Mesurier, W. P. Struvé.
1849. Birmingham	Robt. Stephenson, M.P., F.R.S.	Charles Manby, W. P. Marshall.
1850. Edinburgh	Rev. R. Robinson	Dr. Lees, David Stephenson.
1851. Ipswich	William Cubitt, F.R.S.	John Head, Charles Manby.
1852. Belfast	John Walker, C.E., LL.D., F.R.S.	John F. Bateman, C. B. Hancock, Charles Manby, James Thomson.
1853. Hull	William Fairbairn, C.E., F.R.S.	James Oldham, J. Thomson, W. Sykes Ward.
1854. Liverpool...	John Scott Russell, F.R.S. ...	John Grantham, J. Oldham, J. Thomson.
1855. Glasgow ...	W. J. Macquorn Rankine, C.E., F.R.S.	L. Hill, jun., William Ramsay, J. Thomson.
1856. Cheltenham	George Rennie, F.R.S.	C. Atherton, B. Jones, jun., H. M. Jeffery.
1857. Dublin	Rt. Hon. the Earl of Rosse, F.R.S.	Prof. Downing, W.T. Doyne, A. Tate, James Thomson, Henry Wright.
1858. Leeds	William Fairbairn, F.R.S. ...	J. C. Dennis, J. Dixon, H. Wright.
1859. Aberdeen...	Rev. Prof. Willis, M.A., F.R.S.	R. Abernethy, P. Le Neve Foster, H. Wright.
1860. Oxford	Prof. W. J. Macquorn Rankine, LL.D., F.R.S.	P. Le Neve Foster, Rev. F. Harrison, Henry Wright.
1861. Manchester	J. F. Bateman, C.E., F.R.S....	P. Le Neve Foster, John Robinson, H. Wright.
1862. Cambridge	Wm. Fairbairn, LL.D., F.R.S.	W. M. Fawcett, P. Le Neve Foster.
1863. Newcastle	Rev. Prof. Willis, M.A., F.R.S.	P. Le Neve Foster, P. Westmacott, J. F. Spencer.
1864. Bath	J. Hawkshaw, F.R.S.	P. Le Neve Foster, Robert Pitt.
1865. Birmingham	Sir W. G. Armstrong, LL.D., F.R.S.	P. Le Neve Foster, Henry Lea, W. P. Marshall, Walter May.
1866. Nottingham	Thomas Hawksley, V.P.Inst. C.E., F.G.S.	P. Le Neve Foster, J. F. Iselin, M. O. Tarbotton.
1867. Dundee	Prof. W. J. Macquorn Rankine, LL.D., F.R.S.	P. Le Neve Foster, John P. Smith, W. W. Urquhart.
1868. Norwich ...	G. P. Bidder, C.E., F.R.G.S.	P. Le Neve Foster, J. F. Iselin, C. Manby, W. Smith.
1869. Exeter	C. W. Siemens, F.R.S.	P. Le Neve Foster, H. Bauerman.
1870. Liverpool...	Chas. B. Vignoles, C.E., F.R.S.	H. Bauerman, P. Le Neve Foster, T. King, J. N. Shoolbred.
1871. Edinburgh	Prof. Fleeming Jenkin, F.R.S.	H. Bauerman, Alexander Leslie, J. P. Smith.
1872. Brighton ...	F. J. Bramwell, C.E.	H. M. Brunel, P. Le Neve Foster, J. G. Gamble, J. N. Shoolbred.
1873. Bradford ...	W. H. Barlow, F.R.S.	Crawford Barlow, H. Bauerman, E. H. Carbutt, J. C. Hawkshaw, J. N. Shoolbred.
1874. Belfast	Prof. James Thomson, LL.D., C.E., F.R.S.E.	A. T. Atchison, J. N. Shoolbred, John Smyth, jun.

Date and Place	Presidents	Secretaries
1875. Bristol	W. Froude, C.E., M.A., F.R.S.	W. R. Browne, H. M. Brunel, J. G. Gamble, J. N. Shoolbred.
1876. Glasgow ...	C. W. Merrifield, F.R.S.	W. Bottomley, jun., W. J. Millar, J. N. Shoolbred, J. P. Smith.
1877. Plymouth..	Edward Woods, C.E.	A. T. Atchison, Dr. Merrifield, J. N. Shoolbred.
1878. Dublin	Edward Easton, C.E.	A. T. Atchison, R. G. Symes, H. T. Wood.
1879. Sheffield ...	J. Robinson, Pres. Inst. Mech. Eng.	A. T. Atchison, Emerson Bainbridge, H. T. Wood.
1880. Swansea ...	James Abernethy, V.P. Inst. C.E., F.R.S.E.	A. T. Atchison, H. T. Wood.
1881. York.....	Sir W. G. Armstrong, C.B., LL.D., D.C.L., F.R.S.	A. T. Atchison, J. F. Stephenson, H. T. Wood.
1882. Southamp- ton.	John Fowler, C.E., F.G.S. ...	A. T. Atchison, F. Churton, H. T. Wood.
1883. Southport	James Brunlees, F.R.S.E., Pres. Inst. C.E.	A. T. Atchison, E. Rigg, H. T. Wood.
1884. Montreal ...	Sir F. J. Bramwell, F.R.S., V.P. Inst. C.E.	A. T. Atchison, W. B. Dawson, J. Kennedy, H. T. Wood.
1885. Aberdeen...	B. Baker, M. Inst. C.E.	A. T. Atchison, F. G. Ogilvie, E. Rigg, J. N. Shoolbred.
1886. Birmingham	Sir J. N. Douglass, M. Inst. C.E.	C. W. Cooke, J. Kenward, W. B. Marshall, E. Rigg.
1887. Manchester	Prof. Osborne Reynolds, M.A., LL.D., F.R.S.	C. F. Budenberg, W. B. Marshall, E. Rigg.
1888. Bath.....	W. H. Preece, F.R.S., M. Inst. C.E.	C. W. Cooke, W. B. Marshall, E. Rigg, P. K. Stothert.

ANTHROPOLOGICAL SCIENCE.

SECTION H.—ANTHROPOLOGY.

1884. Montreal ...	E. B. Tylor, D.C.L., F.R.S. ...	G. W. Bloxam, W. Hurst.
1885. Aberdeen...	Francis Galton, M.A., F.R.S.	G. W. Bloxam, Dr. J. G. Garson, W. Hurst, Dr. A. Macgregor.
1886. Birmingham	Sir G. Campbell, K.C.S.I., M.P., D.C.L., F.R.G.S.	G. W. Bloxam, Dr. J. G. Garson, W. Hurst, Dr. R. Saundby
1887. Manchester	Prof. A. H. Sayce, M.A.	G. W. Bloxam, Dr. J. G. Garson, Dr. A. M. Paterson.
1888. Bath.....	Lieut.-General Pitt-Rivers, D.C.L., F.R.S.	G. W. Bloxam, Dr. J. G. Garson, J. Harris Stone.

LIST OF EVENING LECTURES.

Date and Place	Lecturer	Subject of Discourse
1842. Manchester	Charles Vignoles, F.R.S.	The Principles and Construction of Atmospheric Railways.
	Sir M. I. Brunel	The Thames Tunnel.
	R. I. Murchison.....	The Geology of Russia.
1843. Cork	Prof. Owen, M.D., F.R.S.	The Dinornis of New Zealand.
	Prof. E. Forbes, F.R.S.	The Distribution of Animal Life in the Ægean Sea.
	Dr. Robinson.....	The Earl of Rosse's Telescope.
1844. York	Charles Lyell, F.R.S.	Geology of North America.
	Dr. Falconer, F.R.S.	The Gigantic Tortoise of the Siwalik Hills in India.

ate and Place	Lecturer	Subject of Discourse
1845. Cambridge	G.B.Airy, F.R.S., Astron. Royal	Progress of Terrestrial Magnetism.
1846. Southamp- ton.	R. I. Murchison, F.R.S. Prof. Owen, M.D., F.R.S. ... Charles Lyell, F.R.S. W. R. Grove, F.R.S.	Geology of Russia. Fossil Mammalia of the British Isles. Valley and Delta of the Mississippi. Properties of the Explosive substance discovered by Dr. Schönbein; also some Researches of his own on the Decomposition of Water by Heat.
1847. Oxford.....	Rev. Prof. B. Powell, F.R.S. Prof. M. Faraday, F.R.S.....	Shooting Stars. Magnetic and Diamagnetic Phenomena.
1848. Swansea ...	Hugh E. Strickland, F.G.S.... John Percy, M.D., F.R.S.....	The Dodo (<i>Didus ineptus</i>). Metallurgical Operations of Swansea and its neighbourhood.
1849. Birmingham	W. Carpenter, M.D., F.R.S.... Dr. Faraday, F.R.S. Rev. Prof. Willis, M.A., F.R.S.	Recent Microscopical Discoveries. Mr. Gassiot's Battery. Transit of different Weights with varying velocities on Railways.
1850. Edinburgh	Prof. J. H. Bennett, M.D., F.R.S.E.	Passage of the Blood through the minute vessels of Animals in con- nexion with Nutrition.
1851. Ipswich ...	Dr. Mantell, F.R.S. Prof. R. Owen, M.D., F.R.S.	Extinct Birds of New Zealand. Distinction between Plants and Ani- mals, and their changes of Form.
1852. Belfast.....	G.B.Airy, F.R.S., Astron. Royal Prof. G. G. Stokes, D.C.L., F.R.S. Colonel Portlock, R.E., F.R.S.	Total Solar Eclipse of July 28, 1851. Recent discoveries in the properties of Light. Recent discovery of Rock-salt at Carrickfergus, and geological and practical considerations connected with it.
1853. Hull	Prof. J. Phillips, LL.D., F.R.S., F.G.S.	Some peculiar Phenomena in the Geology and Physical Geography of Yorkshire.
1854. Liverpool...	Robert Hunt, F.R.S..... Prof. R. Owen, M.D., F.R.S. Col. E. Sabine, V.P.R.S.	The present state of Photography. Anthropomorphous Apes. Progress of researches in Terrestrial Magnetism.
1855. Glasgow ...	Dr. W. B. Carpenter, F.R.S. Lieut.-Col. H. Rawlinson ...	Characters of Species. Assyrian and Babylonian Antiquities and Ethnology.
1856. Cheltenham	Col. Sir H. Rawlinson	Recent Discoveries in Assyria and Babylonia, with the results of Cuneiform research up to the present time.
1857. Dublin.....	W. R. Grove, F.R.S. Prof. W. Thomson, F.R.S. ... Rev. Dr. Livingstone, D.C.L.	Correlation of Physical Forces. The Atlantic Telegraph. Recent Discoveries in Africa.
1858. Leeds	Prof. J. Phillips, LL.D., F.R.S. Prof. R. Owen, M.D., F.R.S.	The Ironstones of Yorkshire. The Fossil Mammalia of Australia.
1859. Aberdeen...	Sir R. I. Murchison, D.C.L.... Rev. Dr. Robinson, F.R.S. ...	Geology of the Northern Highlands. Electrical Discharges in highly rarefied Media.
1860. Oxford.....	Rev. Prof. Walker, F.R.S. ... Captain Sherard Osborn, R.N.	Physical Constitution of the Sun. Arctic Discovery.
1861. Manchester	Prof. W. A. Miller, M.A., F.R.S. G.B.Airy, F.R.S., Astron. Royal	Spectrum Analysis. The late Eclipse of the Sun.
1862. Cambridge	Prof. Tyndall, LL.D., F.R.S. Prof. Odling, F.R.S.	The Forms and Action of Water. Organic Chemistry.

Date and Place	Lecturer	Subject of Discourse
1863. Newcastle	Prof. Williamson, F.R.S.....	The Chemistry of the Galvanic Battery considered in relation to Dynamics.
	James Glaisher, F.R.S.....	The Balloon Ascents made for the British Association.
1864. Bath.....	Prof. Roscoe, F.R.S.....	The Chemical Action of Light.
	Dr. Livingstone, F.R.S.	Recent Travels in Africa.
1865. Birmingham	J. Beete Jukes, F.R.S.....	Probabilities as to the position and extent of the Coal-measures beneath the red rocks of the Midland Counties.
1866. Nottingham	William Huggins, F.R.S. ...	The results of Spectrum Analysis applied to Heavenly Bodies.
	Dr. J. D. Hooker, F.R.S.....	Insular Floras.
1867. Dundee.....	Archibald Geikie, F.R.S.....	The Geological Origin of the present Scenery of Scotland.
	Alexander Herschel, F.R.A.S.	The present state of knowledge regarding Meteors and Meteorites.
1868. Norwich ...	J. Fergusson, F.R.S.....	Archæology of the early Buddhist Monuments.
	Dr. W. Odling, F.R.S.	Reverse Chemical Actions.
1869. Exeter	Prof. J. Phillips, LL.D., F.R.S.	Vesuvius.
	J. Norman Lockyer, F.R.S....	The Physical Constitution of the Stars and Nebulæ.
1870. Liverpool...	Prof. J. Tyndall, LL.D., F.R.S.	Scientific Use of the Imagination.
	Prof. W. J. Macquorn Rankine, LL.D., F.R.S.	Stream-lines and Waves, in connection with Naval Architecture.
1871. Edinburgh	F. A. Abel, F.R.S.....	Some recent investigations and applications of Explosive Agents.
	E. B. Tylor, F.R.S. ...	The Relation of Primitive to Modern Civilization.
1872. Brighton ...	Prof. P. Martin Duncan, M.B., F.R.S.	Insect Metamorphosis.
	Prof. W. K. Clifford	The Aims and Instruments of Scientific Thought.
1873. Bradford ...	Prof. W. C. Williamson, F.R.S.	Coal and Coal Plants.
	Prof. Clerk Maxwell, F.R.S.	Molecules.
1874. Belfast	Sir John Lubbock, Bart., M.P., F.R.S.	Common Wild Flowers considered in relation to Insects.
	Prof. Huxley, F.R.S.	The Hypothesis that Animals are Automata, and its History.
1875. Bristol	W. Spottiswoode, LL.D., F.R.S.	The Colours of Polarized Light.
	F. J. Bramwell, F.R.S.....	Railway Safety Appliances.
1876. Glasgow ...	Prof. Tait, F.R.S.E.	Force.
	Sir Wyville Thomson, F.R.S.	The <i>Challenger</i> Expedition.
1877. Plymouth...	W. Warington Smyth, M.A., F.R.S.	The Physical Phenomena connected with the Mines of Cornwall and Devon.
	Prof. Odling, F.R.S.....	The new Element, Gallium.
1878. Dublin	G. J. Romanes, F.L.S.	Animal Intelligence.
	Prof. Dewar, F.R.S.	Dissociation, or Modern Ideas of Chemical Action.
1879. Sheffield ...	W. Crookes, F.R.S.	Radiant Matter.
	Prof. E. Ray Lankester, F.R.S.	Degeneration.
1880. Swansea ...	Prof. W. Boyd Dawkins, F.R.S.	Primeval Man.
	Francis Galton, F.R.S.....	Mental Imagery.
1881. York.....	Prof. Huxley, Sec. R.S.	The Rise and Progress of Palæontology.
	W. Spottiswoode, Pres. R.S.	The Electric Discharge, its Forms and its Functions.

Date and Place	Lecturer	Subject of Discourse
1882. Southamp- ton.	Prof. Sir Wm. Thomson, F.R.S.	Tides.
1883. Southport	Prof. H. N. Moseley, F.R.S.	Pelagic Life.
	Prof. R. S. Ball, F.R.S.	Recent Researches on the Distance of the Sun.
	Prof. J. G. McKendrick, F.R.S.E.	Galvani and Animal Electricity.
1884. Montreal ...	Prof. O. J. Lodge, D.Sc.	Dust.
	Rev. W. H. Dallinger, F.R.S.	The Modern Microscope in Re- searches on the Least and Lowest Forms of Life.
1885. Aberdeen...	Prof. W. G. Adams, F.R.S. ...	The Electric Light and Atmospheric Absorption.
1886. Birmingham	John Murray, F.R.S.E.	The Great Ocean Basins.
	A. W. Rücker, M.A., F.R.S.	Soap Bubbles.
1887. Manchester	Prof. W. Rutherford, M.D. ...	The Sense of Hearing.
	Prof. H. B. Dixon, F.R.S. ...	The Rate of Explosions in Gases.
	Col. Sir F. de Winton, K.C.M.G.	Explorations in Central Africa.
1888. Bath	Prof. W. E. Ayrton, F.R.S. ...	The Electrical Transmission of Power.
	Prof. T. G. Bonney, D.Sc., F.R.S.	The Foundation Stones of the Earth's Crust.

LECTURES TO THE OPERATIVE CLASSES.

1867. Dundee.....	Prof. J. Tyndall, LL.D., F.R.S.	Matter and Force.
1868. Norwich ...	Prof. Huxley, LL.D., F.R.S.	A Piece of Chalk.
1869. Exeter	Prof. Miller, M.D., F.R.S. ...	Experimental illustrations of the modes of detecting the Composi- tion of the Sun and other Heavenly Bodies by the Spectrum.
1870. Liverpool...	Sir John Lubbock, Bart., M.P., F.R.S.	Savages.
1872. Brighton ...	W. Spottiswoode, LL.D., F.R.S.	Sunshine, Sea, and Sky.
1873. Bradford ...	C. W. Siemens, D.C.L., F.R.S.	Fuel.
1874. Belfast	Prof. Odling, F.R.S.	The Discovery of Oxygen.
1875. Bristol	Dr. W. B. Carpenter, F.R.S.	A Piece of Limestone.
1876. Glasgow ...	Commander Cameron, C.B., R.N.	A Journey through Africa.
1877. Plymouth...	W. H. Preece	Telegraphy and the Telephone.
1879. Sheffield ...	W. E. Ayrton	Electricity as a Motive Power.
1880. Swansea ...	H. Seebohm, F.Z.S.	The North-East Passage.
1881. York	Prof. Osborne Reynolds, F.R.S.	Raindrops, Hailstones, and Snow- flakes.
1882. Southamp- ton.	John Evans, D.C.L. Treas. R.S.	Unwritten History, and how to read it.
1883. Southport	Sir F. J. Bramwell, F.R.S. ...	Talking by Electricity—Telephones.
1884. Montreal ...	Prof. R. S. Ball, F.R.S.	Comets.
1885. Aberdeen ...	H. B. Dixon, M.A.	The Nature of Explosions.
1886. Birmingham	Prof. W. C. Roberts-Austen, F.R.S.	The Colours of Metals and their Alloys.
1887. Manchester	Prof. G. Forbes, F.R.S.	Electric Lighting.
1888. Bath	Sir John Lubbock, Bart., M.P., F.R.S.	The Customs of Savage Races.

OFFICERS OF SECTIONAL COMMITTEES PRESENT AT THE BATH MEETING.

SECTION A.—MATHEMATICAL AND PHYSICAL SCIENCE.

President.—Professor G. F. Fitzgerald, M.A., F.R.S.

Vice-Presidents.—Capt. W. de W. Abney, C.B., F.R.S.; William Esson, F.R.S.; Dr. Janssen, For.Memb.R.S.; Lord Rayleigh, Sec.R.S.; Professor Sir W. Thomson, F.R.S., F.R.A.S.; Professor Stokes, Pres.R.S.; Professor H. A. Rowland; Rev. R. Harley, F.R.S.

Secretaries.—Robert E. Baynes, M.A. (*Recorder*); R. T. Glazebrook, F.R.S.; Alfred Lodge, M.A.; W. N. Shaw, M.A.

SECTION B.—CHEMICAL SCIENCE.

President.—Professor W. A. Tilden, D.Sc., F.R.S., V.P.C.S.

Vice-Presidents.—Professor H. E. Armstrong, F.R.S.; Dr. J. H. Gladstone, F.R.S.; Professor T. Sterry Hunt, F.R.S.; Professor W. Odling, F.R.S.; Dr. W. H. Perkin, F.R.S.; Professor J. Emerson Reynolds, F.R.S.; Sir H. E. Roscoe, F.R.S.; Dr. W. J. Russell, F.R.S.; Professor A. W. Williamson, F.R.S.

Secretaries.—Professor H. B. Dixon, F.R.S.; H. Forster Morley, D.Sc. (*Recorder*); R. E. Moyle, B.A.; Dr. W. W. J. Nicol, M.A.

SECTION C.—GEOLOGY.

President.—Professor W. Boyd Dawkins, M.A., F.R.S., F.G.S.

Vice-Presidents.—W. Whitaker, F.R.S.; Rev. H. H. Winwood, M.A.; Professor A. Gaudry; Professor O. C. Marsh; Professor S. Nikitin; Dr. Max von Hantken; Professor G. Stefanescu; Professor Baron F. von Richthofen; Professor J. Szabó.

Secretaries.—Professor G. A. Lebour, M.A.; W. Topley, F.R.S. (*Recorder*); W. W. Watts, M.A.; H. B. Woodward, F.G.S.

SECTION D.—BIOLOGY.

President.—W. T. Thiselton-Dyer, C.M.G., M.A., B.Sc., F.R.S., F.L.S.

Vice-Presidents.—Professor Bayley Balfour, F.R.S.; Professor M. Foster, Sec.R.S.; Professor Newton, F.R.S.; Professor E. A. Schäfer, F.R.S.; P. L. Sclater, F.R.S.; Rev. Leonard Blomefield, M.A.

Secretaries.—F. E. Beddard, M.A.; S. F. Harmer, M.A.; Professor H. Marshall Ward, F.R.S. (*Recorder*); Walter Gardiner, M.A.; Professor W. D. Halliburton, M.D.

SECTION E.—GEOGRAPHY.

President.—Colonel Sir C. W. Wilson, R.E., K.C.B., K.C.M.G., D.C.L., F.R.S., F.R.G.S.

Vice-Presidents.—E. Delmar Morgan, F.R.G.S.; H. W. Bates, F.R.S.; Sir Lambert Playfair, K.C.M.G.; Lieut.-Gen. Richard Strachey, R.E., F.R.S.; General J. T. Walker, C.B., R.E., F.R.S.

Secretaries.—J. S. Keltie; H. J. Mackinder, M.A.; E. G. Ravenstein (*Recorder*)...

SECTION F.—ECONOMIC SCIENCE AND STATISTICS.

President.—The Right Hon. Lord Bramwell, LL.D., F.R.S., F.S.S.

Vice-Presidents.—S. Bourne, F.S.S.; G. W. Hastings, M.P.; R. H. Inglis Palgrave, F.R.S.; Professor H. Sidgwick, Litt.D.

Secretaries.—Professor F. Y. Edgeworth, M.A., F.S.S.; T. H. Elliott, F.S.S. (*Recorder*); Professor H. S. Foxwell, M.A., F.S.S.; L. L. F. R. Price, M.A., F.S.S.

SECTION G.—MECHANICAL SCIENCE.

President.—W. H. Preece, F.R.S., M.Inst.C.E.

Vice-Presidents.—W. Anderson, M.Inst.C.E.; Benjamin Baker, M.Inst.C.E.; Sir J. N. Douglass, F.R.S., M.Inst.C.E.; William Pole, Mus.Doc., F.R.S., M.Inst.C.E.; W. Shelford, M.Inst.C.E.; J. L. Stothert, M.Inst.C.E.

Secretaries.—Conrad W. Cooke; W. Bayley Marshall, M.Inst.C.E.; E. Rigg, M.A. (*Recorder*); P. K. Stothert.

SECTION H.—ANTHROPOLOGY.

President.—Lieut.-General Pitt-Rivers, D.C.L., F.R.S., F.G.S., F.S.A.

Vice-Presidents.—J. Beddoe, M.D., F.R.S.; J. Evans, D.C.L., LL.D., F.R.S.; Professor A. H. Sayce, M.A.; Edward B. Tylor, D.C.L., F.R.S.

Secretaries.—G. W. Bloxam, M.A. (*Recorder*); J. G. Garson, M.D.; J. Harris Stone, M.A.

OFFICERS AND COUNCIL, 1888-89.

PRESIDENT.

SIR FREDERICK J. BRAMWELL, BART., D.C.L., F.R.S., M.Inst.C.E.

VICE-PRESIDENTS.

The Right Hon. the EARL OF CORK AND ORRERY,
K.P., Lord Lieutenant of Somerset.
The Most Noble the MARQUIS OF BATH.
The Right Hon. and Right Rev. the LORD BISHOP
OF BATH AND WELLS, D.D.
The Right Rev. the BISHOP OF CLIFTON.
The Worshipful the MAYOR OF BATH.
The Worshipful the MAYOR OF BRISTOL.
Sir F. A. ABEL, C.B., D.C.L., F.R.S., V.P.C.S.
The Venerable the ARCHDEACON OF BATH.

The Rev. LEONARD BLOMEFIELD, M.A.,
F.G.S.
Professor MICHAEL FOSTER, M.A., M.D., LL.D.,
Sec.R.S., F.L.S., F.C.S.
W. S. GORE-LANGTON, Esq., J.P., D.L.
H. D. SKRINE, Esq., J.P., D.L.
Colonel R. P. LAURIE, C.B., M.P.
E. R. WODEHOUSE, Esq., M.P.
JEROM MURCH, Esq., J.P., D.L.

PRESIDENT ELECT.

PROFESSOR WILLIAM HENRY FLOWER, C.B., LL.D., F.R.S., F.R.C.S., Pres.Z.S., F.L.S., F.G.S.,
Director of the Natural History Department of the British Museum.

VICE-PRESIDENTS ELECT.

His Grace the DUKE OF NORTHUMBERLAND, K.G.,
D.C.L., LL.D., Lord-Lieutenant of Northum-
berland.
The Right Hon. the EARL OF DURHAM, Lord
Lieutenant of Durham.
The Right Hon. the EARL OF RAVENSWORTH.
The Right Rev. the LORD BISHOP OF NEWCASTLE,
D.D.
The Right Hon. Lord ARMSTRONG, C.B., D.C.L.,
LL.D., F.R.S.

The Very Rev. the WARDEN of the University of
Durham, D.D.
The Worshipful the MAYOR OF NEWCASTLE.
The Worshipful the MAYOR OF GATESHEAD.
Sir I. LOWTHIAN BELL, Bart., F.R.S., F.C.S.,
M.Inst.C.E.
Sir CHARLES MARK PALMER, Bart., M.P. (*nomi-
nated by the Council*).
The Right Hon. JOHN MORLEY, LL.D., M.P.

LOCAL SECRETARIES FOR THE MEETING AT NEWCASTLE-UPON-TYNE.

Professor P. P. BEDSON, D.Sc., F.C.S. | Professor J. H. MERIVALE, M.A. | HOWARD PEASE, Esq.

LOCAL TREASURER FOR THE MEETING AT NEWCASTLE-UPON-TYNE.

THOMAS HODGKIN, Esq.

ORDINARY MEMBERS OF THE COUNCIL.

ABNEY, Capt. W. DE W., C.B., F.R.S.
BALL, Sir R. S., F.R.S.
BARLOW, W. H., Esq., F.R.S.
BLANFORD, W. T., Esq., F.R.S.
CROOKES, W., Esq., F.R.S.
DARWIN, Professor G. H., F.R.S.
DOUGLASS, Sir J. N., F.R.S.
GAMGEE, Dr. A., F.R.S.
GEIKIE, Dr. A., F.R.S.
GODWIN-AUSTEN, Lieut.-Col. H. H., F.R.S.
HENRICI, Professor O., F.R.S.
JUDD, Professor J. W., F.R.S.
LIVING, Professor G. D., F.R.S.

M'LEOD, Professor H., F.R.S.
MARTIN, J. B., Esq., F.S.S.
OMMANNEY, Admiral Sir E., C.B., F.R.S.
PRERCE, W. H., Esq., F.R.S.
ROBERTS-AUSTEN, Professor W. C., F.R.S.
RÜCKER, Professor A., F.R.S.
SCHÄFER, Professor E. A., F.R.S.
SCHUSTER, Professor A., F.R.S.
SIDGWICK, Professor H., M.A.
THISELTON-DYER, W. T., Esq., C.M.G.,
F.R.S.
THORPE, Professor T. E., F.R.S.
WOODWARD, Dr. H., F.R.S.

GENERAL SECRETARIES.

Capt. Sir DOUGLAS GALTON, K.C.B., D.C.L., LL.D., F.R.S., F.G.S., 12 Chester Street, London, S.W.
A. G. VERNON HARCOURT, Esq., M.A., LL.D., F.R.S., F.C.S., Cowley Grange, Oxford.

SECRETARY.

ARTHUR T. ATCHISON, Esq., M.A., 22 Albemarle Street, London, W.

GENERAL TREASURER.

Professor A. W. WILLIAMSON, Ph.D., LL.D., F.R.S., F.C.S., 17 Buckingham Street, London, W.C.

EX-OFFICIO MEMBERS OF THE COUNCIL.

The Trustees, the President and President Elect, the Presidents of former years, the Vice-Presidents and Vice-Presidents Elect, the General and Assistant General Secretaries for the present and former years, the Secretary, the General Treasurers for the present and former years, and the Local Treasurer and Secretaries for the ensuing Meeting.

TRUSTEES (PERMANENT).

Sir JOHN LUBBOCK, Bart., M.P., D.C.L., LL.D., F.R.S., Pres. L.S.
The Right Hon. Lord RAYLEIGH, M.A., D.C.L., LL.D., Sec.R.S., F.R.A.S.
The Right Hon. Sir LYON PLAYFAIR, K.C.B., M.P., Ph.D., LL.D., F.R.S.

PRESIDENTS OF FORMER YEARS.

The Duke of Devonshire, K.G.	Prof. Stokes, D.C.L., Pres. R.S.	Sir A. C. Ramsay, LL.D., F.R.S.
Sir G. B. Airy, K.C.B., F.R.S.	Prof. Huxley, LL.D., F.R.S.	Sir John Lubbock, Bart., F.R.S.
The Duke of Argyll, K.G., K.T.	Prof. Sir Wm. Thomson, LL.D.	Prof. Cayley, LL.D., F.R.S.
Sir Richard Owen, K.C.B., F.R.S.	Prof. Williamson, Ph.D., F.R.S.	Lord Rayleigh, D.C.L., Sec.R.S.
Lord Armstrong, C.B., LL.D.	Prof. Tyndall, D.C.L., F.R.S.	Sir Lyon Playfair, K.C.B.
Sir William R. Grove, F.R.S.	Sir John Hawkshaw, F.R.S.	Sir Wm. Dawson, C.M.G., F.R.S.
Sir Joseph D. Hooker, K.C.S.I.	Prof. Allman, M.D., F.R.S.	Sir H. E. Roscoe, F.R.S.

GENERAL OFFICERS OF FORMER YEARS.

F. Galton, Esq., F.R.S.	Dr. Michael Foster, Sec.R.S.	P. L. Sclater, Esq., Ph.D., F.R.S.
Dr. T. A. Hirst, F.R.S.	George Griffith, Esq., M.A., F.C.S.	Prof. Bonney, D.Sc., F.R.S.

AUDITORS.

Dr. W. H. Perkin, F.R.S.	Dr. John Evans, F.R.S.	Dr. J. H. Gladstone, F.R.S.

† Including Ladies.

§ Fellows of the American Association were admitted as Hon. Members for this Meeting.

REPORT OF THE COUNCIL.

Report of the Council for the year 1887-88, presented to the General Committee at Bath, on Wednesday, September 5, 1888.

The Council have received reports during the past year from the General Treasurer, and his account for the year will be laid before the General Committee this day.

Since the Meeting at Manchester the following have been elected Corresponding Members of the Association :—

Cleveland Abbe.
 Professor de Bary.
 Professor Bernthsen.
 His Excellency R. Bonghi.
 Professor Lewis Boss.
 Professor J. W. Bruhl.
 Professor G. Capellini.
 H. Caro.
 Professor J. B. Carnoy.
 F. W. Clarke.
 Professor R. Fittig.
 Dr. Anton Fritsch.
 Professor W. His.
 Fr. von Hefner-Alteneck.
 Professor C. Julin.
 Professor Krause.
 Professor A. Ladenburg.
 Professor J. W. Langley.
 Professor Count Solms von Laubach.
 Professor H. Le Chatelier.
 Professor A. Lieben.
 Professor G. Lippmann.
 Dr. Georg Lunge.
 Dr. Henry C. McCook.
 Dr. C. A. Martius.
 Professor D. Mendeléeff.

Professor N. Menschutkin.
 Professor Lothar Meyer.
 Dr. Charles Sedgwick Minot.
 E. S. Morse.
 Professor Noelting.
 Dr. Pauli.
 Professor W. Preyer.
 N. Pringsheim.
 Professor G. Quincke.
 C. V. Riley.
 M. le Marquis de Saporta.
 Ernest Solvay.
 Dr. Alfred Springer.
 Dr. T. M. Treub.
 Professor John Vilanova.
 Professor H. F. Weber.
 Professor L. Weber.
 Professor August Weismann.
 Professor R. Wiedersheim.
 Professor G. Wiedemann.
 Professor J. Wislicenus.
 Dr. Otto Witt.
 Dr. Ludwig H. Wolf.
 Professor C. A. Young.
 Professor F. Zirkel.

The Council have nominated the Venerable Archdeacon Browne a Vice-President of the meeting at Bath.

Invitations for the year 1890 will be presented from Leeds and Cardiff, and from Edinburgh for the year 1891.

The following resolution was referred by the General Committee to the Council for consideration, and action if desirable :—

‘That the Council be requested to take such action as they may think most expedient in order to bring before the Signal Office of the United States a statement of the high value which British meteorologists attach to the manuscript bibliography prepared by the Signal Office.’

The Council, after consideration of the question, are of opinion that it is inexpedient to take action in the matter.

The Council, having considered a motion of Mr. W. T. Thiselton-Dyer calling attention to the present mode of appointing Committees,

with a view to securing more responsible action, are of opinion that the following rule of the Association, 'In case of appointment of Committees for special objects of science, it is expedient that all Members of the Committee should be named, and one of them appointed to act as Secretary, for insuring attention to business,' should be amended as follows:

'In case of appointment of Committees for special objects of science it is expedient, that all Members of the Committee should be named, and one of them appointed to act as Chairman, who shall have notified personally or in writing his willingness to accept the office, the Chairman to have the responsibility of receiving and disbursing the grant (if any has been made) and securing the presentation of the report in due time; and, further, it is expedient that one of the Members should be appointed to act as Secretary for insuring attention to business.

'That it is desirable that the number of Members appointed to serve on a Committee should be as small as is consistent with its efficient working.

'That a tabular list of the Committees appointed on the recommendation of each Section should be sent each year to the Records of the several Sections, to enable them to fill in the statement whether the several Committees appointed on the recommendation of their respective Sections had presented their reports.

'That on the proposal to recommend the appointment of a Committee for a special object of science having been adopted by the Sectional Committee, the number of Members of such Committee be then fixed, but that the Members to serve on such Committee be nominated and selected by the Sectional Committee at a subsequent meeting.'

The Council have received the following report from a Committee of Council appointed to consider the question of grants to marine biological stations in this country, together with a letter from Professor E. Ray Lankester, Secretary of the Marine Biological Association, suggesting that the British Association should complete its donations to the funds of that Association, so as to make up the sum given to the amount of 500*l.*, thereby securing certain rights.

'The British Association has up to the present time granted altogether 300*l.* to the Marine Biological Association, and by a further grant of 200*l.* the British Association would be entitled to nominate a representative on the Council of the Marine Biological Association. The Committee are of opinion that the Council should recommend the General Committee to grant the 200*l.*, and appoint a member to represent them on the Council of the Marine Biological Association.

'With reference to the grants to Marine Biological Stations generally, the Committee are of opinion that in all these cases it is desirable that grants in future should be made to individuals for specific researches rather than for the general maintenance of institutions; and with reference to the Scottish Stations they would further call the attention of the Council to the fact that the Scotch Fishery Board has a parliamentary grant of 2,000*l.* per annum for scientific investigations, the whole of which, it appears from the appropriation accounts, is not at present expended.'

The Council, having received the above Report, have forwarded it, together with the letter of Professor Lankester, to the Committee of Section D.

The report of the Corresponding Societies Committee is herewith submitted to the General Committee.

The Corresponding Societies Committee consisting of Mr. Francis Galton (Chairman), Professor A. W. Williamson, Sir Douglas Galton, Professor Boyd Dawkins, Sir Rawson Rawson, Dr. J. G. Garson, Dr. J. Evans, Mr. J. Hopkinson, Professor R. Meldola (Secretary), Mr. W. Whitaker, Mr. G. J. Symons, General Pitt-Rivers, Mr. W. Topley, Mr. H. G. Fordham, and Mr. William White, with the addition of Professor T. G. Bonney, is hereby nominated for reappointment by the General Committee.

The Council hereby nominate Dr. John Evans, Treasurer R.S., Chairman, Mr. W. Whitaker, F.R.S., Vice-Chairman, and Professor R. Meldola, F.R.S., Secretary to the Conference of Delegates of Corresponding Societies to be held during the Bath meeting.

In accordance with the regulations the five retiring Members of the Council will be:—

Prof. W. Boyd Dawkins, F.R.S.
 Prof. J. Dewar, F.R.S.
 Prof. W. H. Flower, C.B.

Dr. J. H. Gladstone.
 Prof. H. N. Moseley.

The Council recommend the re-election of the other ordinary Members of Council, with the addition of the gentlemen whose names are distinguished by an asterisk in the following list:—

Abney, Capt. W. de W., C.B., F.R.S.
 Ball, Sir R. S., F.R.S.
 Barlow, W. H., Esq., F.R.S.
 Blanford, W. T., Esq., F.R.S.
 Crookes, W., Esq., F.R.S.
 Darwin, Prof. G. H., F.R.S.
 Douglass, Sir James, F.R.S.
 *Gamble, Dr. A., F.R.S.
 *Geikie, Dr. A., F.R.S.
 Godwin-Austen, Lieut.-Col. H. H., F.R.S.
 Henrici, Prof. O., F.R.S.
 Judd, Prof. J. W., F.R.S.
 *Liveing, Prof., F.R.S.

Martin, J. B., Esq., F.S.S.
 M'Leod, Prof. H., F.R.S.
 Ommanney, Admiral Sir E., C.B., F.R.S.
 *Preece, W. H., Esq., F.R.S.
 Roberts-Austen, Prof. W. C., F.R.S.
 *Rücker, Prof., F.R.S.
 Schuster, Prof., F.R.S.
 Sidgwick, Prof. H., M.A.
 Schäfer, Prof., F.R.S.
 Thiselton-Dyer, W. T., Esq., C.M.G.,
 F.R.S.
 Thorpe, Prof. T. E., F.R.S.
 Woodward, Dr. H., F.R.S.

COMMITTEES APPOINTED BY THE GENERAL COMMITTEE AT THE
BATH MEETING IN SEPTEMBER 1888.

1. *Receiving Grants of Money.*

Subject for Investigation or Purpose.	Members of the Committee	Grants
The Possibility of Calculating Tables of certain Mathematical Functions, and, if necessary, of taking steps to carry out the calculations, and to publish the results in an accessible form.	<i>Chairman.</i> —Lord Rayleigh. <i>Secretary.</i> —Mr. A. Lodge. Sir William Thomson, Professor Cayley, Professor B. Price, and Messrs. J. W. L. Glaisher, A. G. Greenhill, and W. M. Hicks.	£ 10
Co-operating with the Scottish Meteorological Society in making Meteorological Observations on Ben Nevis.	<i>Chairman.</i> —Hon. R. Abercromby. <i>Secretary.</i> —Professor Crum Brown. Messrs. Milne-Home, John Murray, and Buchan, and Lord McLaren.	50
Making Experiments for improving the Construction of Practical Standards for use in Electrical Measurements.	<i>Chairman.</i> —Professor Carey Foster. <i>Secretary.</i> —Mr. R. T. Glazebrook. Sir William Thomson, Professor Ayrton, Professor J. Perry, Professor W. G. Adams, Lord Rayleigh, Dr. O. J. Lodge, Dr. John Hopkinson, Dr. A. Muirhead, Mr. W. H. Preece, Mr. Herbert Taylor, Professor Everett, Professor Schuster, Dr. J. A. Fleming, Professor G. F. Fitzgerald, Professor Chrystal, Mr. H. Tomlinson, Professor W. Garnett, Professor J. J. Thomson, Mr. W. N. Shaw, Mr. J. T. Bottomley, and Mr. T. C. Fitzpatrick.	100
Considering the subject of Electrolysis in its Physical and Chemical Bearings.	<i>Chairman.</i> —Professor Fitzgerald. <i>Secretaries.</i> —Professors Armstrong and O. J. Lodge. Professors Sir William Thomson, Lord Rayleigh, J. J. Thomson, Schuster, Poynting, Crum Brown, Ramsay, Frankland, Tilden, Hartley, S. P. Thompson, M'Leod, Roberts-Austen, Rücker, Reinold, Carey Foster, and H. B. Dixon, Captain Abney, Drs. Gladstone, Hopkinson, and Fleming, and Messrs. Crookes, Shelford Bidwell, W. N. Shaw, J. Larmor, J. T. Bottomley, R. T. Glazebrook, J. Brown, E. J. Love, and John M. Thomson.	20

1. *Receiving Grants of Money*—continued.

Subject for Investigation or Purpose	Members of the Committee	Grants
Considering the best Methods of Recording the Direct Intensity of Solar Radiation.	<i>Chairman.</i> —Professor Stokes. <i>Secretary.</i> —Mr. G. J. Symons. Professor Schuster, Mr. G. Johnstone Stoney, Sir H. E. Roscoe, Captain Abney, and Mr. Whipple.	£ 10
Inviting Designs for a good Differential Gravity Meter in supersession of the Pendulum, whereby satisfactory results may be obtained at each station of observation in a few hours instead of the many days over which it is necessary to extend pendulum observations.	<i>Chairman.</i> —General J. T. Walker. <i>Secretary.</i> —Professor Poynting. Sir William Thomson, Sir J. H. Lefroy, General R. Strachey, Professors A. S. Herschel, G. Chrystal, C. Niven, and A. Schuster, and Mr. C. V. Boys.	10
Seasonal Variations in the Temperatures of Lakes, Rivers, and Estuaries in Various Parts of the United Kingdom in Co-operation with the Local Societies represented on the Association.	<i>Chairman.</i> —Mr. John Murray. <i>Secretary.</i> —Dr. H. R. Mill. Professor Chrystal, Dr. A. Buchan, Rev. C. J. Steward, the Hon. R. Abercromby, Mr. J. Y. Buchanan, Mr. David Cunningham, Mr. Isaac Roberts, Professor Fitzgerald, Mr. Sorby, and Mr. Willis Bund.	30 .
Considering the Desirability of introducing a Uniform Nomenclature for the Fundamental Units of Mechanics and of co-operating with other bodies engaged in similar work.	<i>Chairman.</i> —Sir R. S. Ball. <i>Secretary.</i> —Mr. Culverwell. Dr. G. Johnstone Stoney, Professors Everett, Fitzgerald, Hicks, Carey Foster, O. J. Lodge, Poynting, MacGregor, Genese, W. G. Adams, and Lamb, and Messrs. Baynes, A. Lodge, Fleming, W. N. Shaw, Glazebrook, Hayward, Lant Carpenter, Greenhill, Muir, G. Griffith, and J. Larmor.	10
The Action of Light on the Hydracids of the Halogens in presence of Oxygen.	<i>Chairman.</i> —Dr. Russell. <i>Secretary.</i> —Dr. A. Richardson. Captain Abney, and Professors Noel Hartley and W. Ramsay.	10
The Influence of the Silent Discharge of Electricity on Oxygen and other gases.	<i>Chairman.</i> —Professor H. M'Leod. <i>Secretary.</i> —W. A. Shenstone. Professor Ramsay and Mr. J. T. Cundall.	10
Inquiring into and reporting on the present Methods adopted for teaching Chemistry.	<i>Chairman.</i> —Dr. W. J. Russell. <i>Secretary.</i> —Professor W. R. Dunstan. Sir H. E. Roscoe, Professor H. E. Armstrong, Professor Meldola, Professor M'Leod, Dr. J. H. Gladstone, Mr. A. G. Vernon Harcourt, Mr. M. M. Pattison Muir, Professor Smithells, Mr. W. A. Shenstone, and Mr. G. Stallard.	10

1. *Receiving Grants of Money*—continued.

Subject for Investigation or Purpose	Members of the Committee	Grants
Recording the Position, Height above the sea, Lithological Characters, Size, and Origin of the Erratic Blocks of England, Wales, and Ireland, reporting other matters of interest connected with the same, and taking measures for their preservation.	<i>Chairman.</i> —Professor J. Prestwich, <i>Secretary.</i> —Dr. H. W. Crosskey. Professors W. Boyd Dawkins, T. McK. Hughes, and T. G. Bonney and Messrs. C. E. De Rance, D. Mackintosh, W. Pengelly, J. Plant, and R. H. Tiddeman.	£ 10.
The Volcanic Phenomena of Japan.	<i>Chairman.</i> —Mr. R. Etheridge. <i>Secretary.</i> —Professor J. Milne. Mr. T. Gray.	25
The Volcanic Phenomena of Vesuvius and its neighbourhood.	<i>Chairman.</i> —Mr. H. Bauerman. <i>Secretary.</i> —Dr. H. J. Johnston-Lavis. Messrs. F. W. Rudler and J. J. H. Teall.	20
Reporting on the Fossil Phyllopoda of the Palæozoic Rocks.	<i>Chairman.</i> —Mr. R. Etheridge. <i>Secretary.</i> —Professor T. R. Jones. Dr. H. Woodward.	20
Exploring the Higher Eocene Beds of the Isle of Wight.	<i>Chairman.</i> —Dr. H. Woodward. <i>Secretary.</i> —Mr. J. S. Gardner. Mr. Clement Reid.	15
Reporting on the Fossil Plants of the Tertiary and Secondary Beds of the United Kingdom.	<i>Chairman.</i> —Dr. W. T. Blanford. <i>Secretary.</i> —Mr. J. S. Gardner. Professor J. W. Judd, Mr. W. Carruthers, and Dr. H. Woodward.	15
Carrying on the 'Geological Record.'	<i>Chairman.</i> —Dr. J. Evans. <i>Secretary.</i> —Mr. W. Topley. Dr. G. J. Hinde and Messrs. R. B. Newton, J. J. H. Teall, F. W. Rudler, and W. Whitaker.	80
To improve and experiment with a Deep-sea Tow-net for opening and closing under water.	<i>Chairman.</i> —Professor Schäfer. <i>Secretary.</i> —Mr. W. E. Hoyle. Professor W. A. Herdman.	10
The Natural History of the Friendly Islands, or other groups in the Pacific, visited by H.M.S. 'Egeria.'	<i>Chairman.</i> —Professor Newton. <i>Secretary.</i> —Mr. Harmer. Mr. W. T. Thiselton-Dyer and Professor M. Foster.	100
Continuing the Preparation of a Report on our present Knowledge of the Flora of China.	<i>Chairman.</i> —Mr. John Ball. <i>Secretary.</i> —Mr. Thiselton-Dyer. Mr. Carruthers, Professor Oliver, and Mr. Forbes.	25
The Physiology of the Lymphatic System.	<i>Chairman.</i> —Professor Schäfer. <i>Secretary.</i> —Dr. W. D. Halliburton. Professor M. Foster and Professor E. Ray Lankester.	25

1. *Receiving Grants of Money*—continued.

Subject for Investigation or Purpose	Members of the Committee	Grants
Arranging for the Occupation of a Table at the Zoological Station at Naples.	<i>Chairman.</i> —Dr. P. L. Sclater. <i>Secretary.</i> —Mr. Percy Sladen. Professor E. Ray Lankester, Professor Cossar Ewart, Professor M. Foster, Mr. A. Sedgwick, and Professor A. M. Marshall.	100
Reporting on the present state of our Knowledge of the Zoology and Botany of the West India Islands, and taking steps to investigate ascertained deficiencies in the Fauna and Flora.	<i>Chairman.</i> —Professor Flower. <i>Secretary.</i> —Mr. D. Morris. Mr. Carruthers, Dr. Sclater, Mr. Thiselton-Dyer, Dr. Sharp, Mr. F. Du Cane Godman, and Professor Newton.	100
Geography and Geology of the Atlas ranges in the Empire of Morocco, by Mr. Joseph Thomson.	<i>Chairman.</i> —General J. T. Walker. <i>Secretary.</i> —Mr. H. W. Bates. General R. Strachey, Mr. W. T. Thiselton-Dyer, and Professor W. Boyd Dawkins.	100
Inquiring and reporting as to the Statistical Data available for determining the Amount of the Precious Metals in use as Money in the principal countries of the world, the chief forms in which the money is employed, and the amount annually used in the arts.	<i>Chairman.</i> —Mr. Robert Giffen. <i>Secretary.</i> —Prof. F. Y. Edgeworth. Mr. S. Bourne, Professor H. S. Foxwell, Professor Alfred Marshall, Mr. J. B. Martin, Professor J. S. Nicholson, Mr. R. H. Inglis Palgrave, and Professor H. Sidgwick.	20
The best method of ascertaining and measuring Variations in the Value of the Monetary Standard.	<i>Chairman.</i> —Mr. Robert Giffen. <i>Secretary.</i> —Prof. F. Y. Edgeworth. Mr. S. Bourne, Professor H. S. Foxwell, Professor Alfred Marshall, Mr. J. B. Martin, Professor J. S. Nicholson, Mr. R. H. Inglis Palgrave, and Professor H. Sidgwick.	10
The Action of Waves and Currents on the Beds and Foreshores of Estuaries by means of Working Models.	<i>Chairman.</i> —Sir J. N. Douglass. <i>Secretary.</i> —Professor W. C. Unwin. Professor Osborne Reynolds and Messrs. W. Topley, E. Leader Williams, W. Shelford, G. F. Deacon, A. R. Hunt, and W. H. Wheeler.	100
To report on the Development of Graphic Methods in Mechanical Science.	<i>Chairman.</i> —Mr. W. H. Preece. <i>Secretary.</i> —Professor H. S. Hele Shaw. Messrs. B. Baker, W. Anderson, and G. Kapp and Professors J. Perry and R. H. Smith.	25
Editing a new Edition of 'Anthropological Notes and Queries.'	<i>Chairman.</i> —General Pitt-Rivers. <i>Secretary.</i> —Dr. Garson. Dr. Beddoe, Professor Flower, Mr. Francis Galton, Dr. E. B. Tylor.	50

1. *Receiving Grants of Money*—continued.

Subject for Investigation or Purpose	Members of the Committee	Grants
The Habits and Customs and Physical Characteristics of the Nomad Tribes of Asia Minor, and to excavate on sites of ancient occupation.	<i>Chairman.</i> —Dr. Garson. <i>Secretary.</i> —Mr. Bent. Mr. Pengelly, Mr. Rudler, Mr. Bloxam, Mr. J. Stuart Glennie.	£ 30
The Physical Characters, Languages, and Industrial and Social Condition of the North-Western Tribes of the Dominion of Canada.	<i>Chairman.</i> —Dr. E. B. Tylor. <i>Secretary.</i> —Mr. G. W. Bloxam. Sir Daniel Wilson, Dr. G. M. Dawson, General Sir H. Lefroy, Mr. R. G. Haliburton.	150
The Effects of different Occupations and Employments on the Physical Development of the Human Body.	<i>Chairman.</i> —Sir Rawson Rawson. <i>Secretary.</i> —Mr. G. W. Bloxam. General Pitt-Rivers, Dr. J. Beddoe, Dr. H. Muirhead, Mr. C. Roberts, Dr. G. W. Hambleton, Mr. F. W. Rudler, Mr. Horace Darwin, Dr. J. G. Garson, and Dr. A. M. Paterson.	20
Calculating the Anthropological Measurements taken at Bath	<i>Chairman.</i> —General Pitt-Rivers. <i>Secretary.</i> —Dr. Garson. Mr. Bloxam.	5
Carrying on the work of the Corresponding Societies Committee.	<i>Chairman.</i> —Dr. John Evans. <i>Secretary.</i> —Professor R. Meldola. Mr. Francis Galton, Professor A. W. Williamson, Sir Douglas Galton, Professor Boyd Dawkins, Sir Rawson Rawson, Dr. J. G. Garson, Mr. J. Hopkinson, Mr. W. Whitaker, Mr. G. J. Symons, General Pitt-Rivers, Mr. W. Topley, Mr. H. G. Fordham, Mr. William White, and Professor Bonney.	20

2. *Not receiving Grants of Money.*

Subject for Investigation or Purpose	Members of the Committee
To consider the proposals of M. Tondini de Quarenghi relative to the Unification of Time, and the adoption of a Universal Prime Meridian, which have been brought before the Committee by a letter from the Academy of Sciences of Bologna.	<i>Chairman.</i> —Mr. J. Glaisher. <i>Secretary.</i> —Mr. J. Glaisher. Mr. Christie (Astronomer Royal), Sir R. S. Ball, and Dr. G. B. Longstaff.
Considering the advisability and possibility of establishing in other parts of the country Observations upon the Prevalence of Earth Tremors similar to those now being made in Durham in connection with coal-mine explosions.	<i>Chairman.</i> —Mr. G. J. Symons. <i>Secretary.</i> —Professor Lebour. Sir F. J. Bramwell, Mr. E. A. Cowper, Professor G. H. Darwin, Professor Ewing, Mr. Isaac Roberts, Mr. Thomas Gray, Dr. John Evans, Professor Prestwich, Professor Hull, Professor Meldola, Professor Judd, Mr. M. Walton Brown, and Mr. J. Glaisher.

2. *Not receiving Grants of Money*—continued.

Subject for Investigation or Purpose	Members of the Committee
The Molecular Phenomena connected with the Magnetisation of Iron.	<i>Chairman.</i> —Professor Fitzgerald. <i>Secretary.</i> —Professor Barrett. Mr. Trouton.
The Collection and Identification of Meteoric Dust.	<i>Chairman.</i> —Mr. John Murray. <i>Secretary.</i> —Mr. John Murray. Professor Schuster, Sir William Thomson, the Abbé Renard, Mr. A. Buchan, the Hon. R. Abercromby, and Dr. M. Graham.
The Promotion of Tidal Observations in Canada.	<i>Chairman.</i> —Professor Johnson. <i>Secretary.</i> —Professor Johnson. Professors Macgregor, J. B. Cherriman, and H. J. Bovey and Mr. C. Carpmac.
Calculating certain tables in the Theory of Numbers connected with the Divisors of a Number.	<i>Chairman.</i> —Professor Cayley. <i>Secretary.</i> —Mr. J. W. L. Glaisher. Sir W. Thomson and Mr. James Glaisher.
The Harmonic Analysis of Tidal Observation.	<i>Chairman.</i> —Professor J. C. Adams. <i>Secretary.</i> —Professor G. H. Darwin.
Preparing instructions for the practical Work of Tidal Observation.	<i>Chairman.</i> —Professor Darwin. <i>Secretary.</i> —Professor Darwin. Sir W. Thomson and Major Baird.
Comparing and Reducing Magnetic Observations.	<i>Chairman.</i> —Professor W. G. Adams. <i>Secretary.</i> —Professor W. G. Adams. Sir W. Thomson, Sir J. H. Lefroy, Professors G. H. Darwin, G. Chrystal, and S. J. Perry, Mr. C. H. Carpmac, Professor Schuster, Mr. G. M. Whipple, Captain Creak, the Astronomer Royal, Mr. William Ellis, and Mr. W. Lant Carpenter.
The Rate of Increase of Underground Temperature downwards in various Localities of dry Land and under Water.	<i>Chairman.</i> —Professor Everett. <i>Secretary.</i> —Professor Everett. Professor Sir William Thomson, Mr. G. J. Symons, Sir A. C. Ramsay, Dr. A. Geikie, Mr. J. Glaisher, Mr. Pengelly, Professor Edward Hull, Professor Prestwich, Dr. C. Le Neve Foster, Professor A. S. Herschel, Professor G. A. Lebour, Mr. A. B. Wynne, Mr. Gallo-way, Mr. Joseph Dickinson, Mr. G. F. Deacon, Mr. E. Wethered, and Mr. A. Strahan.
Conferring with a Committee of the American Association with a view of forming a Uniform System of Recording the Results of Water Analysis.	<i>Chairman.</i> —Professor Dewar. <i>Secretary.</i> —Professor P. F. Frankland. Professor Odling and Mr. Crookes.

2. *Not receiving Grants of Money*—continued.

Subject for Investigation or Purpose	Members of the Committee
The Continuation of the Bibliography of Spectroscopy.	<i>Chairman.</i> —Professor H. M'Leod. <i>Secretary.</i> —Professor Roberts-Austen. Professor Reinold.
To consider the best Method of Establishing an International Standard for the Analysis of Iron and Steel.	<i>Chairman.</i> —Professor Roberts-Austen. <i>Secretary.</i> —Mr. T. Turner. Mr. J. W. Langley.
Preparing a new series of Wave-length Tables of the Spectra of the Elements.	<i>Chairman.</i> —Sir H. E. Roscoe. <i>Secretary.</i> —Dr. Marshall Watts. Mr. Lockyer, Professors Dewar, Liveing, Schuster, W. N. Hartley, and Wolcott Gibbs and Captain Abney.
Absorption Spectra of Pure Compounds.	<i>Chairman.</i> —General Festing. <i>Secretary.</i> —Dr. H. E. Armstrong. Captain Abney and Professor W. N. Hartley.
The Influence of Silicon on the Properties of Steel.	<i>Chairman.</i> —Professor W. A. Tilden. <i>Secretary.</i> —Mr. Thomas Turner. Professor Roberts-Austen.
Isomeric Naphthalene Derivatives.	<i>Chairman.</i> —Professor W. A. Tilden. <i>Secretary.</i> —Professor H. E. Armstrong.
Certain Physical Constants of Solution, especially the Expansion of Saline Solutions.	<i>Chairman.</i> —Professor W. Ramsay. <i>Secretary.</i> —Professor W. L. Goodwin. Professors Marshall and Tilden.
Reporting on the Bibliography of Solution.	<i>Chairman.</i> —Professor W. A. Tilden. <i>Secretary.</i> —Dr. W. W. J. Nicol. Professors M'Leod, Pickering, Ramsay, and Young and Dr. A. R. Leeds.
The Properties of Solutions	<i>Chairman.</i> —Professor W. A. Tilden. <i>Secretary.</i> —Dr. W. W. J. Nicol. Professor Ramsay.
The Circulation of the Underground Waters in the Permeable Formations of England, and the Quality and Quantity of the Waters supplied to various Towns and Districts from these Formations.	<i>Chairman.</i> —Professor E. Hull. <i>Secretary.</i> —Mr. C. E. De Rance. Dr. H. W. Crosskey, Sir D. Galton, Professor J. Prestwich, and Messrs. J. Glaisher, E. B. Marten, G. H. Morton, J. Parker, W. Pengelly, J. Plant, I. Roberts, C. Fox-Strangways, T. S. Stooke, G. J. Symons, W. Topley, Tylden-Wright, E. Wethered, and W. Whitaker.
Reporting upon the 'Manure Gravels' of Wexford.	<i>Chairman.</i> —Mr. R. Etheridge. <i>Secretary.</i> —Mr. A. Bell. Dr. H. Woodward.
An Ancient Sea-beach near Bridlington.	<i>Chairman.</i> —Mr. J. W. Davis. <i>Secretary.</i> —Mr. G. W. Lamplugh. Mr. W. Cash, Dr. H. Hicks, Mr. Clement Reid, Dr. H. Woodward, and Mr. T. Boynton.

2. *Not receiving Grants of Money.*—continued.

Subject for Investigation or Purpose	Members of the Committee
The Rate of Erosion of the Sea-coasts of England and Wales, and the Influence of the Artificial Abstraction of Shingle or other material in that action.	<p><i>Chairman.</i>—Mr. R. B. Grantham. <i>Secretaries.</i>—Messrs. C. E. De Rance and W. Topley. Messrs. J. B. Redman, W. Whitaker, and J. W. Woodall, Maj.-Gen. Sir A. Clarke, Admiral Sir E. Ommanney, Sir J. N. Douglass, Capt. Sir G. Nares, Capt. J. Parsons, Capt. W. J. L. Wharton, Professor J. Prestwich, and Messrs. E. Easton, J. S. Valentine, and L. F. Vernon Harcourt.</p>
The Flora of the Carboniferous Rocks of Lancashire and West Yorkshire.	<p><i>Chairman.</i>—Professor W. C. Williamson. <i>Secretary.</i>—Mr. W. Cash.</p>
The Development of the Oviduct and connected Structures in certain Fresh-water Teleostei.	<p><i>Chairman.</i>—Professor Lankester. <i>Secretary.</i>—Mr. G. H. Fowler. Professor Milnes Marshall and Mr. Sedgwick.</p>
Taking steps for the Establishment of a Botanical Station at Peradeniya, Ceylon.	<p><i>Chairman.</i>—Professor M. Foster. <i>Secretary.</i>—Professor F. O. Bower. Professor Bayley Balfour, Mr. Thiselton-Dyer, Dr. Trimen, Professor Marshall Ward, Mr. Carruthers, and Professor Hartog.</p>
To make a Digest of the Observations on Migrations of Birds at Lighthouses and Light-vessels, which have been carried on during the past nine years by the Migrations Committee of the British Association (with the consent of the Masters and Elder Brethren of the Trinity House, and the Commissioners of Northern Lights), and to report upon the same at Newcastle.	<p><i>Chairman.</i>—Professor Newton. <i>Secretary.</i>—Mr. John Cordeaux. Mr. Harvie-Brown, Mr. R. M. Barrington, Mr. W. E. Clarke, and Rev. E. P. Knubley.</p>
Collecting Information as to the Disappearance of Native Plants from their Local Habitats.	<p><i>Chairman.</i>—Mr. A. W. Wills. <i>Secretary.</i>—Professor W. Hillhouse. Mr. E. W. Badger.</p>
The Teaching of Science in Elementary Schools.	<p><i>Chairman.</i>—Dr. J. H. Gladstone. <i>Secretary.</i>—Professor Armstrong. Mr. S. Bourne, Miss Becker, Sir J. Lubbock, Dr. Crosskey, Sir R. Temple, Sir H. E. Roscoe, Mr. J. Heywood, and Professor N. Story Maskelyne.</p>

Other Resolutions adopted by the General Committee.

That it is desirable that the Association should become a Governor of the Marine Biological Association, and that a grant of 200*l.* be made to the Marine Biological Association with that view.

That the sum of 100*l.* be placed at the disposal of the Baths Committee of the Bath Corporation to assist in the prosecution of further researches in the Roman Baths.

That Mr. R. E. Baynes and Mr. J. Larmor be requested to draw up a Report on the present state of our knowledge in Thermodynamics, specially with regard to the second law.

That Mr. W. N. Shaw be requested to continue his Report on the present state of our knowledge in Electrolysis and Electro-chemistry.

That Mr. P. T. Main be requested to continue his Report on our experimental knowledge of the Properties of Matter with respect to Volume, Pressure, Temperature, and Specific Heat.

That Mr. Glazebrook be requested to continue his Report on Optics.

That Professor J. J. Thomson be requested to continue his Report on Electrical Theories.

Communications ordered to be printed in extenso in the Annual Report of the Association.

Dr. J. Janssen's paper, 'Sur l'application de l'analyse spectrale à la mécanique moléculaire et sur les spectres de l'oxygène.'

Mr. Stephen Bourne's paper, 'The Use of Index-numbers.'

Mr. L. L. F. R. Price's paper, 'The Relation between Sliding Scales and Economic Theory.'

Professor H. S. Hele Shaw and Mr. E. Shaw's paper on 'The Friction of Metal Coils,' with the necessary illustrations.

The Report of the Conference on Lightning Conductors, as far as is desirable.

Mr. Dalton's paper giving a List of British Mineral Waters.

The Bibliography of the Lesser Antilles, as an appendix to the Report of the Committee on the Zoology and Botany of the West India Islands.

Resolutions referred to the Council for consideration, and action if desirable.

That the Council be recommended to consider what measures, if any, it might be desirable to take with respect to the apparatus from time to time purchased by funds voted by the Association.

That the Council of the Association be requested to urge upon the Corporation of Bath the desirability of laying bare a further portion of the unique Roman Baths at this city, with the view to their permanent preservation; and that the part already laid bare should be protected from the weather.

That the Council be requested to memorialise her Majesty's Government in favour of establishing a permanent Census Sub-Department, and taking the census of the United Kingdom every five years.

Synopsis of Grants of Money appropriated to Scientific Purposes by the General Committee at the Bath Meeting, in September, 1888. The Names of the Members entitled to call on the General Treasurer for the respective Grants are prefixed.

Mathematics and Physics.

General Meetings.

On Wednesday, September 5, at 8 p.m., in the Drill Hall, Sir H. E. Roscoe, M.P., D.C.L., LL.D., Ph.D., F.R.S., F.C.S., resigned the office of President to Sir F. J. Bramwell, D.C.L., F.R.S., M.Inst.C.E., who took the Chair, and delivered an Address, for which see page 1.

On Thursday, September 6, at 8.30 p.m., a Soirée took place in the Assembly Rooms.

On Friday, September 7, at 8.30 p.m., in the Drill Hall, Professor W. E. Ayrton, F.R.S., delivered a Discourse on 'The Electrical Transmission of Power.'

On Monday, September 10, at 8.30 p.m., in the Drill Hall, Professor T. G. Bonney, D.Sc., LL.D., F.R.S., F.S.A., F.G.S., delivered a Discourse on 'The Foundation Stones of the Earth's Crust.'

On Tuesday, September 11, at 8 p.m., a Soirée took place in the Assembly Rooms.

On Wednesday, September 12, at 2.30 p.m., in the Assembly Rooms, the concluding General Meeting took place, when the Proceedings of the General Committee and the Grants of Money for Scientific purposes were explained to the Members.

The Meeting was then adjourned to Newcastle-upon-Tyne. [The Meeting is appointed to commence on Wednesday, September 11, 1889.]

PRESIDENT'S ADDRESS.

ADDRESS

BY

SIR FREDERICK BRAMWELL,

D.C.L., F.R.S., M.INST.C.E.,

PRESIDENT.

THE late Lord Iddesleigh delighted an audience, for a whole evening, by an address on 'Nothing.' Would that I had his talents, and could discourse to you as charmingly as he did to his audience, but I dare not try to talk about 'Nothing.' I do however propose, as one of the two sections of my Address, to discourse to you on the importance of the 'Next-to-Nothing.' The other section is far removed from this microscopic quantity, as it will embrace the 'Eulogy of the Civil Engineer and will point out the value to science of his works.'

I do not intend to follow any system in dealing with these two sections. I shall not even do as Mr. Dick, in 'David Copperfield,' did—have two papers, to one of which it was suggested he should confine his Memorial and his observations as to King Charles's head. The result is, you will find, that the importance of the next-to-nothing, and the laudation of the Civil Engineer, will be mixed up in the most illogical and haphazard way, throughout my Address. I will leave to such of you as are of orderly minds, the task of rearranging the subjects as you see fit, but I trust—arrangement or no arrangement—that by the time I have brought my Address to a conclusion, I shall have convinced you that there is no man who more thoroughly appreciates the high importance of the 'next-to-nothing,' than the Civil Engineer of the present day, the object of my eulogy this evening.

If I may be allowed to express the scheme of this Address in modern musical language, I will say that the 'next-to-nothing' 'motive' will commonly usher in the 'praise-song' of the Civil Engineer; and it seems to me will do this very fitly, for in many cases it is by the patient and discriminating attention paid to the effect of the 'next-to-nothing' that

the Civil Engineer of the present day has achieved some of the labours of which I now wish to speak to you.

An Association for the Advancement of Science is necessarily one of such broad scope in its objects, and is so thoroughly catholic as regards Science, that the only possible way in which it can carry out those objects at all, is to segregate its members into various subsidiary bodies, or sections, engaged on particular branches of Science. Even when this division is resorted to, it is a hardy thing to say that every conceivable scientific subject can be dealt with by the eight Sections of the British Association. Nevertheless, as we know, for fifty-seven years the Association has carried on its labours under Sections, and has earned the right to say that it has done good service to all branches of Science.

Composed, as the Association is, of a union of separate Sections, it is only right and according to the fitness of things that, as time goes on, your Presidents should be selected, in some sort of rotation, from the various Sections. This year it was felt, by the Council and the Members, that the time had once more arrived when Section G—the Mechanical Section—might put forward its claim to be represented in the Presidency; the last time on which a purely engineering Member filled the chair having been at Bristol in 1875, when that position was occupied by Sir John Hawkshaw. It is true that at Southampton, in 1882, our lamented friend, Sir William Siemens, was President, and it is also true that he was a most thorough engineer and representative of Section G; but all who knew his great scientific attainments will probably agree that, on that occasion, it was rather the Physical Section A which was represented, than the Mechanical Section G.

I am aware, it is said, Section G does not contribute much to pure Science by original research, but that it devotes itself more to the application of Science. There may be some foundation for this assertion, but I cannot refrain from the observation, that when Engineers, such as Siemens, Rankine, Sir William Thomson, Fairbairn, or Armstrong, make a scientific discovery, Section A says it is made, not in the capacity of an Engineer, and, therefore, does not appertain to Section G, but in the capacity of a Physicist, and therefore appertains to Section A—an illustration of the danger of a man's filling two positions, of which the composite Prince-Bishop is the well-known type. But I am not careful to labour this point, or even to dispute that Section G does not do much for *original* research. I don't agree it is a fact, but, for the purposes of this evening, I will concede it to be so. But what then? This Association is for the 'Advancement of Science'—the *Advancement* be it remembered; and I wish to point out to you, and I trust I shall succeed in establishing, that for the *Advancement* of Science it is absolutely necessary there should be the *Application* of Science, and that, therefore, the Section, which as much as any other (or, to state the fact more truly, which more than any other) in the Association *applies* Science, is doing

ADDRESS.

a very large share of the work of *advancing* Science, and is fully entitled to be periodically represented in the Presidency of the whole Association.

I trust also I shall prove to you that applications of Science, and discoveries in pure Science, act and re-act the one upon the other. I hope in this to carry the bulk of my audience with me, although there are some, I know, whose feelings, from a false notion of respect for Science, would probably find vent in the 'toast' which one has heard in another place—this 'toast' being attributed to the Pure Scientist—'Here's to the latest scientific discovery: may it never do any good to anybody!'

To give an early illustration of this action and re-action, which I contend occurs: take the well-worn story of Galileo, Torricelli, and the pump-maker. It is recorded that Galileo first, and his pupil Torricelli afterwards, were led to investigate the question of atmospheric pressure, by observing the failure of a pump to raise water by 'suction,' above a certain level. Perhaps you will say the pump-maker was not applying science, but was working without science. I answer, he was unknowingly applying it, and it was from that which arose in this unconscious application that the mind of the Pure Scientist was led to investigate the subject, and thereupon to discover the primary fact, of the pressure of the atmosphere, and the subsidiary facts which attend thereon. It may appear to many of you that the question of the exercise of pressure by the atmosphere should have been so very obvious, that but little merit ought to have accrued to the discoverer; and that the statement, once made, must have been accepted almost as a mere truism. This was, however, by no means the case. Sir Kenelm Digby, in his 'Treatise on the Nature of Bodies,' printed in 1658, disputes the proposition altogether, and says, in effect, he is quite sure, the failure of the pump to raise water was due to imperfect workmanship of some kind or description, and had nothing to do with the pressure of the air; and that there is no reason why a pump should not suck up water to any height. He cites the boy's sucker, which, when applied to a smooth stone, will lift it, and he says the reason why the stone follows the sucker is this. Each body must have some other body in contact with it. Now, the stone being in contact with the sucker, there is no reason why that contact should be broken up, for the mere purpose of substituting the contact of another body, such as the air. It seems pretty clear, therefore, that even to an acute and well-trained mind, such as that of Sir Kenelm Digby, it was by no means a truism, and to be forthwith accepted when once stated, that the rise of water on the 'suction side' of a pump was due to atmospheric pressure. I hardly need point out that the pump-maker should have been a member of 'G.' Galileo and Torricelli, led to reflect by what they saw, should have been members of 'A' of the then 'Association for the Advancement of Science.'

But, passing away from the question of the value of the application

of Science of a date some two and a half centuries ago, let us come a little nearer to our own times.

Electricity—known in its simplest form to the Greeks by the results arising from the friction on amber, and named therefrom; afterwards produced from glass cylinder machines, or from plate machines; and produced a century ago by the ‘Influence’ machine—remained, as did the discoveries of Volta and Galvani, the pursuit of but a few, and even the brilliant experiments of Davy did not suffice to give very great impetus to this branch of physical science.

Ronalds, in 1823, constructed an electric telegraph. In 1837 the first commercial use was made of the telegraph, and from that time electrical science received an impulse such as it had never before experienced. Further scientific facts were discovered; fresh applications were made of these discoveries. These fresh applications led to renewed vigour in research, and there was the action and reaction of which I have spoken. In the year 1871 the Society of Telegraph Engineers was established. In the year 1861 our own Association had appointed a Committee to settle the question of electrical standards of resistance, which Committee, with enlarged functions, continued its labours for twenty years, and of this Committee I had the honour of being a member. The results of the labours of that Committee endure (somewhat modified, it is true), and may be pointed to as one of the evidences of the value of the work done by the British Association. Since Ronalds’s time, how vast are the advances which have been made in electrical communication of intelligence, by land lines, by submarine cables all over the world, and by the telephone! Few will be prepared to deny the statement, that pure electrical science has received an enormous impulse, and has been advanced by the commercial application of electricity to the foregoing, and to purposes of lighting. Since this latter application, scores, I may say hundreds, of acute minds have been devoted to electrical science, stimulated thereto by the possibilities and probabilities of this application.

In this country, no doubt, still more would have been done if the lighting of districts from a central source of electricity had not been, since 1882, practically forbidden by the Act passed in that year. This Act had in its title the facetious statement that it was ‘to facilitate Electrical Lighting’—although it is an Act which, even modified as it has been this year, is still a great discouragement of free enterprise, and a bar to progress. The other day a member of the House of Commons was saying to me: ‘I think it is very much to our discredit in England that we should have allowed ourselves to be outrun in the distribution of electric lighting to houses, by the inhabitants of the United States, and by those of other countries.’ Looking upon him as being one of the authors of the ‘facetious’ Act, I thought it pertinent to quote the case of the French parricide, who, being asked what he has to say in mitigation of punishment, pleads, ‘I’ty a poor orphan’—

ADDRESS.

the parricide and the legislator being both of them authors of conditions of things which they affect to deplore. I will say no more on this subject, for I feel that it would not be right to take advantage of my position here to-night to urge Political Economy views, which should be reserved for Section F. I will merely, and as illustrative of my views of the value of the application of Science to Science itself, say there is no branch of physics pursued with more zeal and with more happy results than that of electricity, with its allies, and there is no branch of Science towards which the public looks with greater hope of practical benefits; a hope that, I doubt not, will be strengthened after we have had the advantage of hearing one of the ablest followers of that science, Professor Ayrton, who, on Friday next, has been good enough to promise to discourse on 'The Electrical Transmission of Power.'

One of the subjects which, as much as (or probably more than) any other, occupies the attention of the engineer, and therefore of Section G, is that of (the so-called) Prime Movers, and I will say boldly that, since the introduction of printing by the use of movable type, nothing has done so much for civilisation as the development of these machines. Let us consider these prime movers—and, first, in the comparatively humble function of replacing that labour which might be performed by the muscular exertion of human beings, a function which at one time was looked upon by many kindly but short-sighted men as taking the bread out of the mouth of the labourer, (as it was called), and as being therefore undesirable. I remember revisiting my old schoolmaster, and his saying to me, shaking his head: 'So you have gone the way I always feared you would, and are making things of iron and brass, to do the work of men's hands.'

It must be agreed that all honest and useful labour is honourable, but when that labour can be carried out without the exercise of any intelligence, one cannot help feeling that the result is likely to be intellectually lowering. Thus it is a sorry thing to see unintelligent labour, even although that labour be useful. It is but one remove from unintelligent labour which is not useful; that kind of labour generally appointed (by means of the tread-wheel or the crank) as a punishment for crime. Consider even the honourable labour (for it is useful, and it is honest) of the man who earns his livelihood by turning the handle of a crane, and compare this with the labour of a smith, who, while probably developing more energy by the use of his muscles, than is developed by the man turning the crane-handle, exercises at the same time the powers of judgment, of eye, and of hand in a manner which I never see without my admiration being excited. I say that the introduction of prime movers as a mere substitute for unintelligent manual labour is in itself a great aid to civilisation and to the raising of humanity, by rendering it very difficult, if not impossible, for a human being to obtain a livelihood by unintelligent work—the work of the horse in the mill, or of the turnspit.

But there are prime movers and prime movers—those of small dimensions, and employed for purposes where animal power or human power might be substituted, and those which attain ends that by no conceivable possibility could be attained at all by the exertion of muscular power.

Compare a galley, a vessel propelled by oars, with the modern Atlantic liner; and first let us assume that prime movers are non-existent and that this vessel is to be propelled galley-fashion. Take her length as some 600 feet, and assume that place be found for as many as 400 oars on each side, each oar worked by three men, or 2,400 men; and allow that six men under these conditions could develop work equal to one horse-power: we should have 400 horse-power. Double the number of men, and we should have 800 horse-power, with 4,800 men at work, and at least the same number in reserve, if the journey is to be carried on continuously. Contrast the puny result thus obtained with the 19,500 horse-power given forth by a large prime mover of the present day, such a power requiring, on the above mode of calculation, 117,000 men at work and 117,000 in reserve; and these to be carried in a vessel less than 600 feet in length. Even if it were possible to carry this number of men in such a vessel, by no conceivable means could their power be utilised so as to impart to it a speed of twenty knots an hour.

This illustrates how a prime mover may not only be a mere substitute for muscular work, but may afford the means of attaining an end, that could not by any possibility be attained by muscular exertion, no matter what money was expended or what galley-slave suffering was inflicted.

Take again the case of a railway locomotive: from 400 to 600 horse-power developed in an implement which, even including its tender, does not occupy an area of more than fifty square yards, and that draws us at sixty miles an hour. Here again, the prime mover succeeds in doing that which no expenditure of money or of life could enable us to obtain from muscular effort.

To what, and to whom, are these meritorious prime movers due? I answer: to the application of science, and to the labours of the civil engineer, using that term in its full and proper sense, as embracing all engineering other than military. I am, as you know, a Civil Engineer, and I desire to laud my profession and to magnify mine office; and I know of no better means of doing this than by quoting to you the definition of 'civil engineering,' given in the Charter of The Institution of Civil Engineers, namely, that it is 'the art of directing the great sources of power in Nature for the use and convenience of man.' These words are taken from a definition or description of engineering given by one of our earliest scientific writers on the subject, Thomas Tredgold, who commences that description by the words above quoted, and who, having given

various illustrations of the civil engineer's pursuits, introduces this pregnant sentence :—

‘This is, however, only a brief sketch of the objects of civil engineering; the real extent to which it may be applied is limited only by the progress of science; its scope and utility will be increased with every discovery in philosophy, and its resources with every invention in mechanical or chemical art, since its bounds are unlimited, and equally so must be the researches of its professors.’

‘The art of directing the great sources of power in Nature for the use and convenience of man.’ Among all secular pursuits, can there be imagined one more vast in its scope, more beneficent, and therefore more honourable, than this? There are those, I know—hundreds, thousands—who say that such pursuits are not to be named as on a par with those of literature; that there is nothing ennobling in them; nothing elevating; that they are of the earth, earthy; are mechanical, and are unintellectual, and that even the mere bookworm, who, content with storing his own mind, neither distributes those stores to others nor himself originates, is more worthily occupied than is the civil engineer.

I deny this altogether, and, while acknowledging, with gratitude, that, in literature, the masterpieces of master minds have afforded, and will afford, instruction, delight, and solace for all generations, so long as civilisation endures, I say that the pursuits of civil engineering are worthy of occupying the highest intelligence, and that they are elevating and ennobling in their character.

Remember the kindly words of Sir Thomas Browne, who said, when condemning the uncharitable conduct of the mere bookworm, ‘I make not, therefore, my head a grave, but a treasure of knowledge, and study not for mine own sake only, but for those who study not for themselves.’ The engineer of the present day finds that he must not make his ‘head a grave,’ but that, if he wishes to succeed, he must have, and must exercise, scientific knowledge; and he realises daily the truth that those who are to come after him must be trained in science, so that they may readily appreciate the full value of each scientific discovery as it is made. Thus the application of science by the engineer not only stimulates those who pursue science, but adds him to their number.

Holding, as I have said I do, the view that he who displaces unintelligent labour is doing good to mankind, I claim for the unknown engineer who, in Pontus, established the first water-wheel of which we have a record, and for the equally unknown engineer who first made use of wind for a motor, the title of pioneers in the raising of the dignity of labour, by compelling the change from the non-intelligent to the intelligent.

With respect to these motors—wind and water—we have two proverbs which discredit them: ‘Fickle as the wind,’ ‘Unstable as water.’

Something more trustworthy was needed—something that we were sure of having under our hands at all times. As a result, Science was

applied, and the 'fire' engine, as it was first called, the 'steam' engine, as it was re-named, a form of 'heat' engine, as we now know it to be, was invented.

Think of the early days of the steam-engine—the pre-Watt days. The days of Papin, Savory, Newcomen, Smeaton! Great effects were produced, no doubt, as compared with no fire engine at all; effects so very marked as to extort from the French writer, Belidor, the tribute of admiration he paid to the 'fire' engine erected at the Fresnes Colliery by English engineers. A similar engine worked the pumps in York Place (now the Adelphi) for the supply of water to portions of London. We have in his work one of the very clearest accounts, illustrated by the best engravings (absolute working drawings), of the engine which had excited his admiration. These drawings show the open-topped cylinder, with condensation taking place below the piston, but with the valves worked automatically.

It need hardly be said that, noteworthy as such a machine was, as compared with animal power, or with wind or water motors, it was of necessity a most wasteful instrument as regards fuel. It is difficult to conceive in these days how, for years, it could have been endured that at each stroke of the engine the chamber that was to receive the steam at the next stroke was carefully cooled down beforehand by a water injection.

Watt, as we know, was the first to perceive, or, at all events, to cure, this fundamental error which existed prior to his time in the 'fire' engine. To him we owe condensation in a separate vessel, the doing away with the open-topped cylinder, and the making the engine double-acting; the parallel motion; the governor; and the engine indicator, by which we have depicted for us the way in which the work is being performed within the cylinder. To Watt, also, we owe that great source of economic working—the knowledge of the expansive force of steam; and to his prescience we owe the steam jacket, without which expansion, beyond certain limits, is practically worthless. I have said 'prescience'—foreknowledge—but I feel inclined to say that, in this case, prescience may be rendered 'pre-Science,' for I think that Watt *felt* the utility of the steam jacket, without being able to say on what ground that utility was based.

I have already spoken in laudatory terms of Tredgold, as being one of the earliest of our scientific engineering writers, but, as regards the question of steam jacketing, Watt's prescience was better than Tredgold's science, for the latter condemns the steam jacket, as being a means whereby the cooling surfaces are enlarged, and whereby, therefore, the condensation is increased.

I think it is not too much to say, that engineers who, since Watt's days, have produced machines of such marvellous power—and, compared with the engines of Watt's days, of so great economy—have, so far as principles are concerned, gone upon those laid down by Watt. Details

of the most necessary character—necessary to enable those principles to be carried out—have, indeed, been devised since the days of Watt. Although it is still a very sad confession to have to make, that the very best of our steam engines only utilises about one-sixth of the work which resides (if the term may be used) in the fuel that is consumed, it is, nevertheless, a satisfaction to know that great economical progress has been made, and that the 6 or 7 lbs. of fuel per horse-power per hour consumed by the very best engines of Watt's days, when working with the aid of condensation, is now brought down to about one-fourth of this consumption; and this in portable engines, for agricultural purposes, working without condensation—engines of small size, developing only 20 horse-power; in such engines the consumption has been reduced to as little as 1.85 lb. per brake horse-power per hour, equal to 1.65 lb. per indicated horse-power per hour, as was shown by the trials at the Royal Agricultural Society's meeting at Newcastle last year—trials in which I had the pleasure of participating.

In these trials, Mr. William Anderson, one of the Vice-Presidents of Section G, and I were associated, and, in making our report of the results, we adopted the balance-sheet system, which I suggested and used so long ago as 1873 (see vol. 52, pages 154 and 155, of the 'Minutes of Proceedings of the Institution of Civil Engineers'), and to which I alluded in my address as President of Section G at Montreal.

I have told you that the engineer of the present day appreciates the value of the 'next-to-nothings.' There is an old housekeeping proverb that, if you take care of the farthings and the pence, the shillings and the pounds will take care of themselves. Without the balance-sheet one knows that for the combustion of 1 lb. of coal, the turning into steam of a given quantity of water at a given pressure is obtained. It is seen, at once, that the result is much below that which should be had, but to account for the deficiency is the difficulty. The balance-sheet, dealing with the most minute sources of loss—the farthings and the pence of economic working—brings you face to face with these, and you find that improvement must be sought in paying attention to the 'next-to-nothings.'

Just one illustration. The balance-sheet will enable you at a glance to answer this among many important questions. Has the fuel been properly burnt?—with neither too much air, nor too little.

At the Newcastle trials our knowledge as to whether we had the right amount of air for perfect combustion was got by an analysis of the waste gases, taken continuously throughout the whole number of hours' run of each engine, affording, therefore, a fair average. The analysis of any required portion of gases thus obtained was made in a quarter of an hour's time by the aid of the admirable apparatus invented by Mr. Stead, and, on the occasion to which I refer, manipulated by him. In one instance an excess of air had been supplied, causing a percentage

of loss of 6·34. In the instance of another engine there was a deficiency of air, resulting in the production of carbonic oxide, involving a loss of 4 per cent. The various percentages of loss, of which each one seems somewhat unimportant, in the aggregate amounted to 28 per cent., and this with one of the best boilers. This is an admirable instance of the need of attention to apparently small things.

I have already said that we now know the steam engine is really a heat engine. At the York Meeting of our Association I ventured to predict that, unless some substantive improvement were made in the steam engine (of which improvement, as yet, we have no notion), I believed its days, for small powers, were numbered, and that those who attended the centenary of the British Association in 1931 would see the present steam engines in museums, treated as things to be respected, and of antiquarian interest to the engineers of those days, such as are the open-topped steam cylinders of Newcomen and of Smeaton to ourselves. I must say I see no reason, after the seven years which have elapsed since the York Meeting, to regret having made that prophecy, or to desire to withdraw it.

The working of heat engines, without the intervention of the vapour of water, by the combustion of the gases arising from coal, or from coal and from water, is now not merely an established fact, but a recognised and undoubted, commercially economical, means of obtaining motive power. Such engines, developing from 1 to 40-horse-power, and worked by the ordinary gas supplied by the gas mains, are in most extensive use in printing works, hotels, clubs, theatres, and even in large private houses, for the working of dynamos to supply electric light. Such engines are also in use in factories, being sometimes driven by the gas obtained from 'culm' and steam, and are giving forth a horse-power for, it is stated, as small a consumption as one pound of fuel per hour.

It is hardly necessary to remind you—but let me do it—that, although the saving of half a pound of fuel per horse-power appears to be insignificant, when stated in that bald way, one realises that it is of the highest importance when that half-pound turns out to be 33 per cent. of the whole previous consumption of one of those economical engines to which I have referred.

The gas engine is no new thing. As long ago as 1807, a M. de Rivaz proposed its use for driving a carriage on ordinary roads. For anything I know he may not have been the first proposer. It need hardly be said that in those days he had not illuminating gas to resort to, and he proposed to employ hydrogen. A few years later, a writer in 'Nicholson's Journal,' in an article on 'flying machines,' having given the correct statement that all that is needed to make a successful machine of this description is to find a sufficiently light motor, suggests that the direction in which this may be sought is the employment of illuminating gas, to operate by its explosion on the piston of an engine. The idea of the gas engine

was revived, and formed the subject of a patent by Barnett in the year 1838. It is true this gentleman did not know very much about the subject, and that he suggested many things which, if carried out, would have resulted in the production of an engine which could not have worked ; but he had an alternative proposition which would have worked.

Again, in the year 1861, the matter was revived by Lenoir, and in the year 1865, by Hugon, both French inventors. Their engines obtained some considerable amount of success and notoriety, and many of them were made and used ; but in the majority of cases they were discarded as wasteful and uncertain. The Institution of Civil Engineers, for example, erected a Lenoir in the year 1868, to work the ventilating fan, but after a short time they were compelled to abandon it and to substitute a hydraulic engine.

At the present time, as I have said, gas engines are a great commercial success, and they have become so by the attention given to small things, in popular estimation—to important things, in fact, with which, however, I must not trouble you. Messrs. Crossley Brothers, who have done so much to make the gas engine the commercial success that it is, inform me that they are prosecuting improvements in the direction of attention to detail, from which they are obtaining greatly improved results.

But, looking at the wonderful petroleum industry, and at the multifarious products which are obtained from the crude material, is it too much to say, that there is a future for motor engines, worked by the vapour of some of the more highly volatile of these products—true vapour—not a gas, but a condensable body, capable of being worked over and over again? Numbers of such engines, some of as much as 4 horse-power, made by Mr. Yarrow, are now running, and are apparently giving good results ; certainly excellent results as regards the compactness and lightness of the machinery ; for boat purposes they possess the great advantage of being rapidly under way. I have seen one go to work within two minutes of the striking of the match to light the burner.

Again, as we know, the vapour of this material has been used as a gas in gas engines, the motive power having been obtained by direct combustion.

Having regard to these considerations, was I wrong in predicting that the heat engine of the future will probably be one independent of the vapour of water? And, further, in these days of electrical advancement, is it too much to hope for the direct production of electricity from the combustion of fuel?

As the world has become familiar with prime movers, the desire for their employment has increased. Many a householder could find useful occupation for a prime mover of $\frac{1}{4}$ or $\frac{1}{2}$ horse-power, working one or two hours a day ; but the economical establishment of a steam engine is not possible until houses of very large dimensions are reached, where

space exists for the engine, and where, having regard to the amount of work to be done, the incidental expenses can be borne. Where this cannot be, either the prime mover, with the advantages of its use, must be given up as a thing to be wished for, but not to be procured, or recourse must be had to some other contrivance—say to the laying on of power, in some form or another, from a central source.

I have already incidentally touched upon one mode of doing this, namely, the employment of illuminating gas, as the working agent in the gas engine; but there are various other modes, possessing their respective merits and demerits—all ingenious, all involving science in their application, and all more or less in practical use—such as the laying-on of special high-pressure water, as is now being extensively practised in London, in Hull, and elsewhere. Water at 700 lbs. pressure per inch is a most convenient mode of laying on a large amount of power, through comparatively small pipes. Like electricity, where, when a high electromotive force is used, a large amount of energy may be sent through a small conductor, so with water, under high pressure, the mains may be kept of reasonable diameters, without rendering them too small to transmit the power required through them.

Power is also transmitted by means of compressed air, an agent which, on the score of its ability to ventilate, and of its cleanliness, has much to recommend it. On the other hand, it is an agent which, having regard to the probability of the deposition of moisture in the form of 'snow,' requires to be worked with judgment.

Again, there is an alternative mode for the conveyance of power by the exhaustion of air—a mode which has been in practical use for over sixty years.

We have also the curious system pursued at Schaffhausen, where quick-running ropes are driven by turbines, these being worked by the current of the river Rhine; and at New York, and in other cities of the United States, steam is laid on under the streets, so as to enable domestic steam engines to be worked, without the necessity of a boiler, a stoker, or a chimney, the steam affording also means of heating the house when needed.

Lastly, there is the system of transmitting power by electricity, to which I have already adverted. I was glad to learn, only the other day, that there was every hope of this power being applied to the working of an important subterranean tramway.

These distributions from central sources need, as a rule, statutory powers to enable the pipes or wires to be placed under the roads; and, following the deplorable example of the Electrical Facilities Act, it is now the habit of the enlightened corporation, and the enterprising town clerk of most boroughs to say to capitalists who are willing to embark their capital in the plant for the distribution of power from a central source—for their own profit, no doubt, but also, no doubt, for the good of the

community—‘We will oppose you in Parliament, unless you will consent that, at the end of twenty-one years, we may acquire compulsorily your property, and may do so, if it turns out to be remunerative, without other payment than that for the mere buildings and plant at that time existing.’ This is the way English enterprise is met, and then English engineers are taunted, by Englishmen—often by the very men who have had a share in making this ‘boa-constrictor’ of a ‘Facilities Act’—that their energy is not to be compared with that which is to be found in the United States and other countries. Again, however, I must remember that I am not addressing Section F.

There is one application of science, by engineers, which is of extreme beauty and interest, and that cannot be regarded with indifference by the agriculturists of this country. I allude to the Heat-withdrawing Engines (I should like to say, ‘Cold-Producers,’ but I presume, if I did, I should be criticised), which are now so very extensively used for the importation of fresh meat, and for its storage when received here. It need hardly be said, that that which will keep cool and sweet the carcases of sheep will equally well preserve milk, and many other perishable articles of food. We have in these machines daily instances that, if you wish to make a ship’s hold cold, you can do it by burning a certain quantity of coals—a paradox, if ever there was one.

In this climate of ours, where the summer has been said to consist of ‘three hot days and a thunderstorm,’ there is hardly need to make a provision for cooling our houses, although there is an undoubted need for making a provision to heat them. Nevertheless, those of us who have hot-water heating arrangements for use in the winter would be very glad indeed if, without much trouble or expense, they could turn these about, so as to utilise them for cooling their houses in summer. Mr. Loftus Perkins, so well known for his labours in the use of very high-pressure steam (600 to 1,000 lbs. on the inch), and also so well known for those most useful high-pressure warming arrangements which, without disfiguring our houses by the passage of large pipes, keep them in a state of warmth and comfort throughout the winter, has lately taken up the mode of, I will say it, producing ‘cold’ by the evaporation of ammonia, and, by improvements in detail, has succeeded in making an apparatus which, without engine or pumps, produces ‘cold’ for some hours in succession, and requires, to put it in action, the preliminary combustion of only a few pounds of coke or a few feet of gas.

As I have said, our climate gives us but little need to provide or employ apparatus to cool our houses, but one can well imagine that the Anglo-Indian will be glad to give up his punkah for some more certain, and less draughty, mode of cooling.

I now desire to point out how, as the work of the engineer grows, his needs increase. New material, or better material of the old kind, has to be found to enable him to carry out these works of greater mag-

nitude. At the beginning of this century, stone, brick, and timber were practically the only materials employed for that which I may call standing engineering work—*i.e.*, buildings, bridges, aqueducts, and so on—while timber, cast iron, and wrought iron were for many years the only available materials for the framing and principal parts of moving machines and engines, with the occasional use of lead for the pipes and of copper for pipes and for boilers.

As regards the cast iron, little was known of the science involved (or that ought to be involved) in its manufacture. It was judged of by results. It was judged of largely by the eye. It was 'white,' it was 'mottled,' it was 'grey.' It was known to be 'fit for refining,' fit for 'strong castings,' or fit for castings in which great fluidity in the molten metal was judged to be of more importance than strength in the finished casting. With respect to wrought iron, it was judged of by its results also. It was judged of by the place of its manufacture—but when the works of the district were unknown, the iron, on being tested, was classed as 'good fibrous,' although some of the very best was 'steel-like,' or 'bad,' 'hot-short,' or 'cold-short.' A particular district would produce one kind of iron, another district another kind of iron. The ore, the flux, and the fuel were all known to have influence, but to what extent was but little realised; and if there came in a new ore, or a new flux, it might well be that for months the turn-out of the works into which these novelties had been introduced would be prejudiced. Steel again—that luxury of the days of my youth—was judged by the eye. The wrought bars, made into 'blister' steel by 'cementation,' were broken, examined, and grouped accordingly. Steel was known, no doubt, to be a compound of iron and carbon, but the importance of exactness in the percentage was but little understood, nor was it at all understood how the presence of comparatively small quantities of foreign matter might necessitate the variation of the proportions of carbon. The consequence was that anomalous results every now and then arose to confound the person who had used the steel, and falsifying the proverb 'true as steel,' steel became an object of distrust. Is it too much to say that Bessemer's great invention of steel made by the 'converter,' and that Siemens's invention of the open-hearth process, reacted on pure science, and set scientific men to investigate the laws which regulate the union of metals and of metalloids?—and that the labours of these scientific men have improved the manufacture, so that steel is now thoroughly and entirely trusted? By its aid engineering works are accomplished which, without that aid, would have been simply impossible. The Forth Bridge, the big gun, the compound armour of the ironclad with its steel face, the projectile to pierce that steel face—all equally depend upon the 'truth' of steel as much as does the barely visible hair spring of the chronometer, which enables the longitude of the ship in which it is carried to be ascertained. Now, what makes the difference between trustworthy and untrustworthy steel

for each particular purpose? Something which, until our better sense comes to our aid, we are inclined to look upon as ridiculously insignificant—a 'next-to-nothing.' Setting extraneous ingredients aside, and considering only the union of iron and carbon, the question whether there shall be added or deducted one-tenth of 1 per cent. (pardon my clumsy way of using the decimal system) of carbon is a matter of great importance in the resulting quality of the steel. This is a striking practical instance of how apparently insignificant things may be of the highest importance. The variation of this fraction of a percentage may render your boiler steel untrustworthy, may make the difference between safety in a gun and danger in a gun, and may render your armour-piercing projectile unable to pierce even the thinnest wrought-iron armour.

While thus brought incidentally to the subject of guns, let me derive from it another instance of the value of small things. I have in my hand a piece of steel ribbon. It is probable that only those who are near to me can see it. Its dimensions are one-fourth by one-sixteenth of an English inch, equal to an area of one sixty-fourth of a square inch. This mode of stating the dimensions I use for the information of the ladies. To make it intelligible to my scientific friends, I must tell them that it is approximately $\cdot 00637$ of a metre, by approximately $\cdot 00159$ of a metre, and that its sectional area is $\cdot 0000101283$ (also approximately) of a square metre. This insignificant (and speaking in reference to the greater number of my audience), practically invisible piece of material—that I can bend with my hand, and even tie into knots—is, nevertheless, not to be despised. By it one reinforces the massive and important-looking A-tube of a 9·2-inch gun, so that from that tube can be projected with safety a projectile weighing 380 pounds at a velocity, when leaving the muzzle, of between one-third and one-half of a mile in a second, and competent to traverse nearly $12\frac{1}{2}$ miles before it touches the ground. It may be said, 'What is the use of being able to fire a projectile to a distance which commonly is invisible (from some obstacle or another) to the person directing the gun?' I will suggest to you a use. Imagine a gun of this kind placed by some enemy who, unfortunately, had invaded us, and had reached Richmond. He has the range table for his gun; he, of course, is provided with our Ordnance maps, and he lays and elevates the gun at Richmond, with the object of striking, say, the Royal Exchange. Suppose he does not succeed in his exact aim. The projectile goes 100 yards to one side or to the other; or it falls 250 yards short, or passes 250 yards over; and it would be 'bad shooting' indeed, in these days, if nearly every projectile which was fired did not fall somewhere within an area such as this. In this suggested parallelogram of 100,000 square yards, or some 20 acres, there is some rather valuable property; and the transactions which are carried on are not unimportant. It seems to me that business would not be conducted with that calmness and coolness which are necessary for success, if, say every five minutes, a 380-pound

1888.

shell fell within this area, vomiting fire, and scattering its walls in hundreds of pieces, with terrific violence, in all directions. Do not suppose I am saying that similar effects cannot be obtained from a gun where wire is not employed. They can be. But my point is, that they can also be obtained by the aid of the insignificant thing which I am holding up at this moment—this piece of steel ribbon, which looks more suitable for the framework of an umbrella.

I have already spoken to you, when considering steel as a mere alloy of iron and carbon, as to the value of even a fraction of 1 per cent. of the latter; but we know that in actual practice steel almost always contains other ingredients. One of the most prominent of these is manganese. It had for years been used, in quantities varying from a fraction of 1 per cent. up to 2·5 per cent., with advantage as regards ductility, and as regards its ability to withstand forging. A further increase was found not to augment the advantage: a still further increase was found to diminish it: and here the manufacturer stopped, and, so far as I know, the pure scientist stopped, on the very reasonable ground that the point of increased benefit appeared to have been well ascertained, and that there could be no advantage in pursuing an investigation which appeared only to result in decadence. But this is another instance of how the application of science reacts in the interests of pure science itself. One of our steel manufacturers, Mr. Hadfield, determined to pursue this apparently barren subject, and in doing so discovered this fact—that, while with the addition of manganese in excess of the limit before stated, and up to as much as 7 per cent., deterioration continued, after this latter percentage was passed improvement again set in.

Again, the effects of the addition of even the very smallest percentages of aluminium upon the steel with which it may be alloyed are very striking and very peculiar, giving to the steel alloy thus produced a very much greater hardness, and enabling it to take a much brighter and more silver-like polish. Further, the one-twentieth part of 1 per cent. of aluminium, when added to molten wrought iron, will reduce the fusing-point of the whole mass some 500 degrees, and will render it extremely fluid, and thus enable wrought iron (or what are commercially known as 'Mitis'—castings of the most intricate character) to be produced.

No one has worked more assiduously at the question of the effect of the presence of minute quantities, even traces, of alloys with metals than Professor Roberts-Austen, and he appears, by his experiments, to be discovering a general law, governing the effect produced by the mixture of particular metals, so that, in future, it is to be hoped, when an alloy is, for the first time, to be attempted, it will be possible to predict with reasonable certainty what the result will be, instead of that result remaining to be discovered by experiment.

I have just, incidentally, mentioned aluminium. May I say that we

engineers look forward, with much interest, to all processes tending to bring this metal, or its alloys, within possible commercial use?

One more instance of the effect of impurities in metals. The engineer engaged in electrical matters is compelled, in the course of his daily work, frequently to realise the importance of the 'next-to-nothing.' One striking instance of this is afforded by the influence which an extremely minute percentage of impurity has on the electrical conductivity of copper wire: this conductivity being in some cases reduced by as much as 50 per cent., in consequence of the admixture of that which, under other circumstances, would be looked upon as insignificant.

Reverting to the question of big guns. According to the present mode of manufacture, after we have rough-bored and turned the 'A' tube (and perhaps I ought to have mentioned that by the 'A' tube is meant the main piece of the gun, the innermost layer, if I may so call it, that portion which is the full length of the gun, and upon which the remainder of the gun is built up)—after, as I have said, we have rough-bored and turned this 'A' tube, we heat it to a temperature lying between certain specified limits, but actually determined by the behaviour of samples previously taken, and then suddenly immerse it perpendicularly into a well some 60 feet deep, full of oil, the oil in this well being kept in a state of change by the running into it, at the bottom, of cold oil conveyed by a pipe proceeding from an elevated oil tank. In this way the steel is oil-hardened, with the result of increasing its ultimate tensile strength, and also with the result of raising its so-called elastic limit. In performing this operation it is almost certain that injurious internal strains will be set up: strains tending to produce self-rupture of the material. Experiments have been carried out in England, by Captain Andrew Noble, and by General Maitland of the Royal Gun Factory, by General Kalakoutsky, in Russia, and also in the United States, to gauge what is the value, as represented by dimensions, of these strains, and we find that they have to be recorded in the most minute fractions of an inch, and yet, if the steel be of too 'high' a quality (as it is technically called), or if there has been any want of uniformity in the oil-hardening process, these strains, unless got rid of or ameliorated by annealing, may, as I have said, result in the self-rupture of the steel.

I have spoken of the getting rid of these strains by annealing, a process requiring to be conducted with great care, so as not to prejudice the effects of the oil-hardening. But take the case of a hardened steel projectile, hardened so that it will penetrate the steel face of compound armour. In that case annealing cannot be resorted to, for the extreme hardness of the projectile must not be in the least impaired. The internal strains in these projectiles are so very grave, that for months after they are made there is no security that they will not spontaneously fracture. I have here the point of an 8-inch projectile, which projectile weighs 210 lbs., this with others was received from the makers as long ago as March of

this year, and remained an apparently perfect and sound projectile until about the middle of August—some five months after delivery—and, of course, a somewhat longer time since manufacture—and between August 6th and 8th this piece which I hold in my hand, measuring $3\frac{3}{4}$ inches by $3\frac{1}{2}$ inches, spontaneously flew off from the rest of the projectile, and has done so upon a surface of separation which, whether having regard to its beautiful regularity, or to the conclusions to be drawn from it as to the nature of the strains existing, is of the very highest scientific interest. Many other cases of self-rupture of similar projectiles have been recorded.

Another instance of the effect of the 'next-to-nothing' in the hardening and tempering or annealing of steel. As we know, the iron and the carbon (leaving other matters out of consideration) are there. The carbon is (even in tool-steel) a very small proportion of the whole. The steel may be bent, and will retain the form given to it. You heat it and plunge it in cold water; you attempt to bend it and it breaks; but if, after the plunging in cold water, you temper it by carefully reheating it, you may bring it to the condition fit either for the cutting-tool for metal, or for the cutting-tool for wood, or for the watch-spring; and these important variations of condition which are thus obtained depend upon the 'next-to-nothing' in the temperature to which it is reheated, and therefore in the nature of the resulting combination of the ingredients of which the steel is composed.

Some admirable experiments were carried out on this subject by the Institution of Mechanical Engineers, with the assistance of one of our Vice-Presidents, Sir Frederick Abel, and the subject has also been dealt with by an eminent Russian writer.

There is, to my mind, another and very striking popular instance (if I may use the phrase) of the importance of attention to detail—that is, to the 'next-to-nothing.' Consider the bicycles and tricycles of the present day—machines which afford the means of healthful exercise to thousands, and which will, probably within a very short time, prove of the very greatest possible use for military purposes. The perfection to which these machines have been brought is almost entirely due to strict attention to detail; in the selection of the material of which the machines are made; in the application of pure science (in its strictest sense) to the form and to the proportioning of the parts, and also in the arrangement of these various parts in relation the one to the other. The result is that the greatest possible strength is afforded with only the least possible weight, and that friction in working has been reduced to a minimum. All of us who remember the hobby-horse of former years, and who contrast that machine with the bicycle or tricycle of the present day, realise how thoroughly satisfactory is the result of this attention to detail—this appreciation of the 'next-to-nothing.'

Let me give you another illustration of the importance of small things, drawn from gunnery practice.

At first sight one would be tempted to say that the density of the air on the underside of a shot must, notwithstanding its motion of descent, be so nearly the same as that of the air upon the upper side as to cause the difference to be unworthy of consideration; but we know that the projectiles from rifled guns tend to travel sideways as they pass through the air, and that the direction of their motion, whether to the right or to the left, depends on the 'hand' of the rifling. We know also, that the friction against liquid or against gaseous bodies varies with the densities of these bodies, and it is believed that, minute as is the difference in density to which I have referred, it is sufficient to determine the lateral movement of the projectile. This lateral tendency must be allowed for, in these days of long ranges, in the sighting and laying of guns, if we desire accuracy of aim, at those distances at which it is to be expected our naval engagements will have to be commenced, and perhaps concluded. We can no longer afford to treat the subject as Nelson is said to have treated it, in one of his letters to the Secretary of the Admiralty, who had requested that an invention for laying guns more accurately should be tried. Nelson said he would be glad to try the invention, but that, as his mode of fighting consisted in placing his ship close alongside that of the enemy, he did not think the invention, even if it were successful, would be of much use to him.

While upon the question of guns, I am tempted to remark upon that which is by no means a small thing (for it is no less than the rotation of the earth), which in long-distance firing may demand attention, and that to an extent little suspected by the civilian.

Place the gun north and south, say in the latitude of London, and fire a 12-mile round such as I have mentioned, and it will be found that, assuming the shot were passing through a vacuum, a lateral allowance of more than 200 feet must be made to compensate for the different velocity of the circumference of the earth at 12 miles north or south of the place where the gun was fired, as compared with the velocity of the circumference of the earth at that place itself—the time of flight being in round numbers one minute.

At the risk of exciting a smile, I am about to assert that engineering has even its poetical side. I will ask you to consider with me whether there may not be true poetry in the feelings of the engineer who solves a problem such as this: Consider this rock, never visible above the surface of the tide, but making its presence known by the waves which rise around it: it has been the cause of destruction to many a noble vessel which had completed, in safety, its thousands of leagues of journey, and was, within a few score miles of port; then dashed to pieces upon it? Here is this rock. On it build a lighthouse. Lay your foundations through the water, in the midst of the turmoil of the sea; make your preparations; appear to be attaining success, and find the elements are against you and that the whole of your preliminary works are ruined

or destroyed in one night ; but again commence, and then go on and go on until at last you conquer ; your works rise above ordinary tide-level ; then upon these sure foundations, obtained it may be after years of toil, erect a fair shaft, graceful as a palm and sturdy as an oak ; surmount it with a light, itself the produce of the highest application of science ; direct that light by the built-up lens, again involving the highest application of science ; apply mechanism, so arranged that the lighthouse shall from minute to minute reveal to the anxious mariner its exact name and its position on the coast. When you have done all this, will you not be entitled to say to yourself, 'It is I who have for ever rendered innocuous this rock which has been hitherto a dread source of peril' ? Is there no feeling, do you think, of a poetical nature excited in the breast of the engineer who has successfully grappled with a problem such as this ?

Another instance : the mouth of a broad river, or, more properly speaking, the inlet of the sea, has to be crossed at such a level as not to impede the passage of the largest ships. Except in one or two places the depth is profound, so that multiple foundations for supporting a bridge become commercially impossible, and the solution of the problem must be found by making, high in the air, a flight of span previously deemed unattainable. Is there no poetry here ? Again, although the results do not strike the eye in the same manner, is there nothing of poetry in the work, that has to be thought out and achieved, when a wide river or an ocean channel has to be crossed by a subterranean passage ? Works of great magnitude of this character have been performed with success, and to the benefit of those for whose use they were intended. One of the greatest and most noble of such works, encouraged, in years gone by, by the Governments of our own country and of France, has lately fallen into disfavour with an unreasoning public, who have not taken the pains to ascertain the true state of the case.

Surely it will be agreed that the promotion of ready intercourse and communication between nations constitutes the very best and most satisfactory guarantees for the preservation of peace ; when the peoples of two countries come to know each other intimately, and when they, therefore, enter into closer business relations, they are less liable to be led away by panic or by anger, and they hesitate to go to war the one with the other. It is in the interests of both that questions of difference which may arise between them should be amicably settled, and having an intimate knowledge of each other, they are less liable to misunderstand, and the mode of determination of their differences is more readily arranged. Remember, the means of ready intercourse and of communication, and the means of easy travel, are all due to the application of science by the engineer. Is not therefore his profession a beneficent one ?

Further, do you not think poetical feeling will be excited in the breast of that engineer who will in the near future solve the problem (and it certainly will be solved when a sufficiently light motor is obtained) of travel-

ling in the air—whether this solution be effected by enabling the self-suspended balloon to be propelled and directed, or perhaps, better still, by enabling not only the propulsion to be effected and the direction to be controlled, but by enabling the suspension in the air itself to be attained by mechanical means ?

Take other functions of the Civil Engineer—functions which, after all, are of the most important character, for they contribute directly to the prevention of disease, and thereby not only prolong life, but do that which is probably more important—afford to the population a healthier life while lived.

In one town, about which I have full means of knowing, the report has just been made that in the year following the completion of a comprehensive system of sewerage, the deaths from zymotic diseases had fallen from a total of 740 per annum to a total of 372—practically one half. Has the engineer no inward satisfaction who knows such results as these have accrued from his work ?

Again, consider the magnitude and completeness of the water supply of a large town, especially a town that has to depend upon the storing-up of rain water : the prevision which takes into account, not merely the variation of the different seasons of the year, but the variation of one year from another ; that, having collated all the stored-up information, determines what must be the magnitude of the reservoirs to allow for at least three consecutive dry years, such as may happen ; and that finds the sites where these huge reservoirs may be safely built.

All these—and many other illustrations which I could put before you if time allowed—appear to me to afford conclusive evidence that, whether it be in the erection of the lighthouse on the lonely rock at sea ; whether it be in the crossing of rivers or seas, or arms of seas, by bridges or by tunnels ; whether it be the cleansing of our towns from that which is foul ; whether it be the supply of pure water to every dwelling, or the distribution of light or of motive power ; or whether it be in the production of the mighty ocean steamer, or in the spanning of valleys, the piercing of mountains, and affording the firm, secure road for the express train ; or whether it be the encircling of the world with telegraphs—the work of the Civil Engineer is not of the earth earthy, is not mechanical to the exclusion of science, is not unintellectual ; but is of a most beneficent nature, is consistent with true poetical feeling, and is worthy of the highest order of intellect.

REPORTS

ON THE

STATE OF SCIENCE.

REPORTS

ON THE

STATE OF SCIENCE.

Fourth Report of the Committee, consisting of Professors A. JOHNSON (Secretary), J. G. MACGREGOR, J. B. CHERRIMAN, and H. T. BOVEY and Mr. C. CARPMAEL, for the purpose of promoting Tidal Observations in Canada.

LAST year the Committee reported that Lieut. Gordon, R.N., commander of one of the Dominion cruisers, had been authorised to make some preliminary observations and to spend some small sums of money in getting assistance for this purpose; and also that he had been directed to put himself in communication with Prof. Darwin with the expectation that next year a special grant would be made for systematic tidal observations. It was understood that no more could be done in the interval. The Committee, therefore, have taken no action during the past year. It is considered, however, desirable that they should be reappointed in order to keep the matter before the Government during the next session of Parliament. The Board of Trade of Montreal is still earnestly pressing this as well as other questions connected with a hydrographic survey on the attention of ministers.

Report of the Committee, consisting of Sir R. S. BALL, Dr. G. JOHNSTONE STONEY, Professors EVERETT, FITZGERALD, HICKS, CAREY FOSTER, O. J. LODGE, POYNTING, MACGREGOR, GENESE, W. G. ADAMS, and LAMB, Messrs. BAYNES, A. LODGE, FLEMING, W. N. SHAW, GLAZEBROOK, HAYWARD, LANT CARPENTER, CULVERWELL (Secretary), and GREENHILL, Dr. MUIR, and Messrs. G. GRIFFITH and J. LARMOR, appointed for the purpose of considering the desirability of introducing a Uniform Nomenclature for the Fundamental Units of Mechanics, and of co-operating with other bodies engaged in similar work.

THE Committee recommend the use of the following names:—

The unit of velocity on the C.G.S. system of units, i.e., the velocity of one centimetre per second, to be called one Kine.

The unit of momentum on the C.G.S. system of units, *i.e.*, the momentum of one gramme moving at one kine, to be called one Bole.

The unit of pressure on the C.G.S. system of units, *i.e.*, the pressure of one dyne per square centimetre, to be called one Barad.

The Committee do not recommend that any additional names be given to English units.

They ask to be reappointed, as they think that there are some other units upon which there is prospect of agreement as to the names to be recommended.

Fourth Report of the Committee, consisting of Professor BALFOUR STEWART (Secretary), Professor W. GRYLLS ADAMS, Mr. W. LANT CARPENTER, Mr. C. H. CARPMAK, Mr. W. H. M. CHRISTIE (Astronomer Royal), Professor G. CHRYSTAL, Captain CREAK, Professor G. H. DARWIN, Mr. WILLIAM ELLIS, Sir J. H. LEFROY, Professor S. J. PERRY, Professor SCHUSTER, Professor Sir W. THOMSON, and Mr. G. M. WHIPPLE, appointed for the purpose of considering the best means of Comparing and Reducing Magnetic Observations.

SINCE their last report the Committee have to record the death of their Secretary, Professor Balfour Stewart, whose loss will be deeply felt in the scientific world, especially by those who are engaged in researches in terrestrial magnetism and in the work of magnetic observatories. A meeting of the Committee was held on February 2, 1888, at which Professor W. Grylls Adams was requested to act as Secretary to the Committee, and to forward to the directors of magnetic observatories copies of the third report of the Committee, calling special attention to the paragraphs relating to the determination of scale coefficients.

At the second meeting of the Committee on July 11, 1888, Mr. W. L. Carpenter handed to the Committee a paper which had been prepared by Professor Balfour Stewart on a comparison between the wind values and declination disturbances at the Kew Observatory. The Committee have thought it right to recommend that this paper and the table accompanying it be printed as an appendix to the report.

The Committee learn that all the scientific material found among Dr. Stewart's papers is in the possession of Professor A. Schuster. Professor Schuster has continued his reduction of the diurnal variation of terrestrial magnetism and has nearly completed a paper on the subject, which he purposes to present to the Royal Society.

A paper has also been communicated to the Committee by Major Dawson on magnetic observations taken at Fort Rae in 1882-83, which is printed as Appendix II. to this report.

APPENDIX I. *Results of a comparison between the wind values and declination disturbances at the Kew Observatory.* By BALFOUR STEWART, M.A., LL.D., F.R.S., and WILLIAM LANT CARPENTER, B.A., B.Sc.

In a note communicated to the Royal Society on February 11, 1885, we gave the results of a preliminary comparison between the dates of cyclonic

storms in Great Britain and those of declination disturbances at the Kew Observatory. As we continued this investigation we came to the conclusion that the best method of procedure would be to compare together what may be termed wind-weather and declination-disturbance-weather, in order to see if there is any apparent connexion between them; our hope of a positive result being strengthened by the belief that there is accumulating evidence in favour of a connexion of some kind between the convection currents of the earth and the oscillations of terrestrial magnetism.

We shall, therefore, begin by defining precisely what we mean by wind weather and by disturbance weather. We have obtained, through the kindness of the Kew Committee, records of the total amount in miles gone over by the wind at Kew for each day of the years 1858–73 (sixteen years in all), and we have likewise obtained from the same source daily aggregates of the disturbance of magnetic declination at Kew separated by Sabine's method.

To begin with the wind values, we have first of all smoothed these down into daily averages of three days. Let us call this Table A.

We have next obtained a Table B, where each day's value is the average of 25 days of Table A, all being properly placed as regards dates.

Next, taking the difference between the entries of Tables A and B, we obtain a series representing departures from the mean—*plus* when in excess, and *minus* when in deficiency—which may be taken to represent *wind weather*. The declination aggregate daily disturbance numbers (for which the unit is $\frac{1}{100}$ of an inch measured on the curve) have been treated in exactly the same way as the wind numbers, and the differences finally obtained have been taken to represent *disturbance weather*. The values representing wind weather have then been formed into series of twelve terms, each so chosen that *maximum* wind values come together at the middle of each series. The yearly sums of these series, as well as four-yearly sums and total sum for 16 years, are exhibited in Table I_a.

The disturbance weather values have then been arranged into series of twelve terms each, so that each entry is two days previous in date to the corresponding entry of Table I_a. The yearly, four-yearly, and total sums of these series are given in Table I_b.

The values representing wind weather have next been formed into series of twelve terms each, so chosen that *minimum* wind values come together at the middle of each series. The yearly, four-yearly, and total sums of these series are given in Table II_a.

Finally, the disturbance-weather values have been arranged into series of twelve turns each, so that each entry is two days prior in date to the corresponding entry in Table II_a, and the sums of these are entered in Table II_b.

The general results of the comparison for the sixteen years are shown in the accompanying table, and if averages be taken from these for the three minimum sunspot years 1865–6–7, and for the three maximum years on either side thereof, we get . . .

	Wind weather	Declination weather
1858–59–60	68·6	64·0
1865–66–67	65·0	51·8
1869–70–71	67·0	63·5

APPENDIX II. *Magnetic Disturbances at Fort Rae in 1882-83.*

At the International Polar Conference in Vienna, in the spring of 1884, the subject of the treatment of magnetic disturbances was much discussed, but among the numerous schemes proposed none was universally accepted, and the matter was left undecided.

I have thought it worth while to make trial, on the observations of declination and horizontal intensity made at Fort Rae in 1882-83, of a method founded on that proposed by Dr. Wild, and the results obtained will not, I hope, be without interest.

From a comparison of lists of magnetically undisturbed days, supplied by most of the circumpolar stations, Dr. Wild selected from four to six days in each month, when the diurnal variation appeared to follow a normal course; and the hourly means obtained from these days are given in the Fort Rae observations. When, however, these values are plotted down they do not afford a very regular curve, because, though these days are free from disturbance as a whole, a good many decidedly disturbed observations are included. The readings for hours of magnetic disturbances were therefore struck out, the question of disturbance being decided by reference to the original observation-book, for, as nine observations were taken at each hour, it was easy to see whether the instruments were steady or not. Rather under 4 per cent. of the readings were so struck out, and from the remainder a fairly satisfactory set of hourly mean values was obtained for each month.

The mean of these values at any hour for any two adjacent months was then assumed to be the normal value at that hour on the middle day of the two months. Thus, for example, the mean horizontal intensity from the selected undisturbed days being, for January, at 11 A.M., .07653; for February, at the same hour, .07661; and for March, .07669; then the normal value for that hour was taken as .07657 on January 30, and .07665 on March 2.

Having thus obtained a set of hourly values at intervals of about a month, the values for the intermediate days were easily interpolated, and in this manner a normal value of declination and horizontal intensity was obtained for every hour of the year.

By subtracting each of these values from the corresponding observed value the 'disturbance' at each hour was obtained, sometimes with a +, sometimes with a - sign. These positive and negative disturbances were then entered in separate sheets, and their means are given in the appended tables (I.—IV.) These means are obtained by dividing the sums of disturbance by the number of observations; not by the number of + or - disturbances.

In order to determine whether the larger and smaller disturbances follow different laws the disturbances were classified according to their magnitude. Table V. shows the number of each class occurring at each hour.

H. P. DAWSON, *Maj. R.A.*

April 20, 1887.

Fourth Report of the Committee, consisting of Professor G. FORBES (Secretary), Captain ABNEY, Dr. J. HOPKINSON, Professor W. G. ADAMS, Professor G. C. FOSTER, Lord RAYLEIGH, Mr. PREECE, Professor SCHUSTER, Professor DEWAR, Mr. A. VERNON HARCOURT, Mr. H. TRUEMAN WOOD, Sir JAMES DOUGLASS, Professor H. B. DIXON, and Mr. DIBDIN, appointed for the purpose of reporting on Standards of Light.

THE Committee, which has now been in existence for four years, has at length arrived at certain definite conclusions as to the value of the different standards of light at present available. These conclusions have been arrived at mainly as the result of a large number of experiments undertaken by various members of the Committee.

The experiments of the past year are added to this report in the form of two appendices. The first contains an extensive series of experiments which have been tabulated, showing the relative constancy of the following proposed standards:—

1. Ordinary candles made by Messrs. Miller.
2. Ordinary candles made by Messrs. Brecknell and Turner.
3. Sperm candles, of six to the pound, of larger diameter, made by Messrs. Miller.
4. The Pentane Standard.
5. The Pentane Lamp.
6. The Amyl-acetate Lamp.

The other appendix relates to some experiments carried on with a view to making platinum heated to its melting-point a practical standard.

The Committee wishes to state that the result of all its experiments has been to confirm the conclusions arrived at by Mr. Dibdin in his report to the Metropolitan Board of Works in 1887.

Your Committee, in making its final report, is anxious to draw attention to a number of conclusions which will now be treated in order:—

(1) The present standard candle, as defined by Act of Parliament, is not worthy, in the present state of science, of being called a standard, and does not meet the practical requirements of those whose duty it is to test illuminants. The objections to the candle as a standard are so numerous, and most of them are so well understood, that space need not be taken up now in repeating them. It will suffice to say that the spermaceti employed is not a definite chemical substance and is mixed with other materials, and the constitution of the wick is not sufficiently well-defined, so that so-called standard candles, conforming to the definitions of the Act of Parliament, can be made which vary largely in illuminating power. The Committee wishes to add the important observation, which has been incontestably proved by the independent observations of different members of the Committee, that the illuminating power of a candle in a closed photometer, or in any small, ill-ventilated room, is considerably less than in an ordinary room.

That which forces itself upon the attention of any one who attempts to determine the value of any source of light by comparison with standard candles is the fluctuation from minute to minute, which is due to the varying length and form of the wick and the filling and emptying of the

cup of the candle according to the movement of the surrounding air. But these variations are to some extent neutralized by taking the average of many testings. A source of error, which is at once less easily recognised and more grave in its practical result, is the change in the average value of the standard candle, which is due to the improvements made from time to time in the manufacture of spermaceti. The manufacturer aims at separating as perfectly as possible the solid parts of his crude material, which constitute spermaceti, from the liquid parts which form sperm oil. To obtain as much oil and as 'dry' a spermaceti as possible is the object sought, and we are informed by one of the principal manufacturers of sperm candles that within the last ten years considerable improvements have been made in the process by which the separation is effected. As a consequence of the use in the making of standard candles of a drier sperm, it has been found necessary to provide them with thicker wicks, in order that the required rate of consumption may be maintained. Probably the drier sperm has a higher melting-point and furnishes a less limpid liquid. A thicker wick means less light for a given consumption; and thus the result of the improvements in spermaceti has been that standard candles give less light than they gave ten years ago, and probably still less light than they gave at an earlier date, when the average consumption of a sperm candle of six to the pound was 140 grs. per hour.

(2) Professor Violle's standard of molten platinum is, in the opinion of the Committee, not a practical standard of light. On this point your Committee is anxious to have it understood that it is quite prepared to agree to the adoption of the light emitted by a square centimetre of molten platinum as a unit of light, but not as a standard of light. Hence, in its recommendation, it is not challenging the conclusions arrived at by the International Congress of Electricians. The experiments detailed in the second appendix to this report confirm the Committee in its belief that there is no means at present known by which molten platinum can be used practically as a standard. In fact, a comparison of Violle's unit with any standard could be made only with great labour and but rarely. Violle's unit not having been universally adopted, your Committee would not propose to change the name of the unit hitherto in use, but would call it a standard candle, giving it that value which appears to have been intended by the Legislature, and was used in the adjustment of the Pentane standard.

(3) There seems unfortunately no prospect of any reliable electric standard of light being constructed. In the report of 1885 your Committee delayed making a definite recommendation until further information should be gained by experiment about the laws of radiation from carbon heated by an electric current. The information gained since then has led it to believe that but little help is to be gained from this quarter. Some of the reasons are given in the report of 1886; others are the variation in light by the blackening of the glass bulbs in which the carbons are enclosed, and by the wasting of the carbon filaments. Also the amount of radiation from carbon depends upon its surface and upon the treatment to which it has been subjected.

(4) The Amyl-acetate standard is very constant, but its red colour is a serious objection to its use. This conclusion has been arrived at as the result of a very large number of experiments in the hands of the Committee. The following experiments by the Committee show this well:—

The Amyl-acetate lamp was compared with the Standard Pentane flame by placing the two equidistant from the screen. The flame of the Amyl-acetate lamp was set at a height of 45 mm., and an observer watching the two halves of the screen turned up and down the Pentane flame until he judged the screen to be equally illuminated by the two lights. The Amyl-acetate lamp gave a distinctly redder light than the Pentane flame. In comparing the two lights four observers obtained results which were appreciably different, each result being constantly obtained in successive readings by the same observer. Two observers made the light from the Amyl-acetate flame exactly equal to the normal Pentane flame of $63\frac{1}{2}$ mm.; a third observer made the Amyl-acetate flame equal to a Pentane flame of 63 mm.; and a fourth made it equal to a Pentane flame of $62\frac{1}{2}$ mm.

On raising the Amyl-acetate flame to 50 mm. the same differences in the estimation of the two coloured flames were found, but the change in height of 5 mm. in the Amyl-acetate flame was compensated by a change in height of 2 mm. in the Pentane flame.

(5) The Pentane standard of Mr. Vernon Harcourt is reliable and convenient, and fulfils all the conditions required in the adoption of a standard of light. This standard attains this end by its having no wick and consuming a material of definite chemical composition. The experiments of your Committee also show that the light was not altered when the specific gravity of the pentane was .632 or .628, instead of the specified value of .630.

(6) Your Committee is not of opinion that the Pentane standard is the only one which can be made possessing the necessary qualifications, but it is the only one which has come under its notice, and it wishes most earnestly to urge the importance of undertaking such action as is possible to ensure the immediate rejection by the Board of Trade of the Parliamentary candle as a standard, and the adoption in all future work of the Pentane standard.

(7) Your Committee wishes further to draw attention to the following :

APPENDIX I.

Photometric comparison of Candles, the Pentane Standard, the New Pentane Lamp, and the Amyl-acetate Lamp.

By the courtesy of Mr. Dibdin and the Metropolitan Board of Works the testing-room at Spring Gardens was placed at the disposal of the Committee for conducting experiments. The photometer employed was a four-way one designed by Mr. Dibdin, the standard source of light in the centre being a portion of the flame of an argand burning coal gas enriched by passing over pentane. This central flame was kept at a height of about 3 inches, and only light from the middle of the flame was allowed to fall on the photometer discs. In a preliminary series of experiments made in January 1888 it was found that the light proceeding from the central burner along each of the four photometer bars was equal. The fittings and measurements of all parts of the photometer were also carefully verified by the Committee.

It was decided that the actual tests should be performed by two of the official gas-testers in the service of the Metropolitan Board. Messrs. G. W. Wood and R. Grimwood were selected by Mr. Dibdin to carry out the work, which they performed in a most careful and satisfactory manner.

Mr. Livingston kindly undertook to chronicle and keep the records of the experiments made, and also assist in the testings, and to him the Committee is beholden for the very considerable trouble he took on its behalf.

The experiments were conducted as follows:—The central flame being adjusted, one observer made a determination of its illuminating power by candles in the first arm and by the Pentane lamp in the second arm, making the readings alternately. At the same time the second observer made a determination of the illuminating power of the central burner by the Amyl-acetate lamp in the third arm and by the Pentane standard in the fourth arm, also making the readings alternately. The observers changed positions after each set of observations. The candle readings were corrected in the usual way for sperm consumed. On all the four bars the standards were kept fixed in position and the readings were made by moving the discs. The candles employed were those now manufactured by Mr. Miller and by Messrs. Brecknell and Turner for gas-testing, but tests were made also of other candles, of the same composition as the gas-testing candles, but larger in diameter, which were made by Mr. Miller. The Pentane lamp was of the new form manufactured by Messrs. Woodhouse and Rawson.

It was found that the central burner was nearly but not exactly constant in illuminating power from day to day, but during the hour and a half or two hours the tests lasted each day the light did not vary appreciably, according to the most uniform standards. In order to show the uniformity of the standards under trial, the average of the day's tests with each standard is taken and the individual tests compared with this mean. The divergencies of each standard from the mean of several tests *by the same standard* are evidence of the want of uniformity of that standard.

In the following table the corrected result of each test is given; 118 complete tests by each of the four standards were taken. By the side of each result is a number (obtained by dividing that result by the average of the day's tests and multiplying by 100) which expresses the ratio of that result to the average of the day by the same standard, the day's average being called 100. A glance at the table shows the uniformity or want of uniformity of the standards. Out of the 118 complete candle tests 86 differed by 1 per cent. from the day's average, 57 differed by 2 per cent., and 19 by 5 per cent. Variations of 9 and 10 per cent. occurred occasionally. Of the other standards the Amyl-acetate lamp showed a variation of 2 per cent. from the day's average on four occasions out of the 118 tests, and a variation of 1 per cent. on 11 occasions. The Pentane lamp twice only showed a variation of 1 per cent., the Pentane standard once only.

In the second table the averages of each day are tabulated and the general average of each standard is given. The Pentane standard and the Pentane lamp gave practically the same light; and the light was not altered when pentane of specific gravity .632 and of specific gravity .628 was employed, instead of pentane of specific gravity .630. The Amyl-acetate lamp was set too high, but although this was discovered soon after the experiments were begun it was thought better to maintain the flame at the same height than to alter it during the tests. The three lamps tested gave uniform results. The broader candles made by Mr. Miller gave less light than those ordinarily used for gas-testing, and they did not appear to burn more uniformly in this photometer.

TABLE I.

Tests of Central Burner made by four Standards in Four-way Photometer.

APPENDIX II.

Incandescent Platinum.

The attention of the Committee was naturally directed to the proposed French standard suggested by M. Violle, namely, the light emitted by a square centimetre of liquid platinum at the solidifying point. The apparatus required for the production of such a standard is of necessity very cumbrous and inconvenient and extremely ill-suited for photometrical measurements. The attention of the Committee was therefore directed to methods of obtaining the same result in a more convenient manner and on a smaller scale, with the view of constructing apparatus which could without inconvenience be introduced into an ordinary photometer.

For this purpose the apparatus employed by Mr. Dibdin in his recent experiments was first tried. This consists of an arrangement by means of which a roll of platinum foil was stretched over two rollers, having an interval of about three inches between them, across which the foil was stretched. In front of the foil a steatite plate having a circular aperture of a quarter of an inch was placed, and immediately behind the foil was an oxyhydrogen burner so arranged that when a full flame was turned on it impinged upon the foil in a direction horizontal with the aperture in the steatite plate and thus heated the platinum to fusion. Although the mechanical part worked as satisfactorily as could be desired, the results obtained on the photometer were so variable that no reliance could be placed upon them. The method was then modified by placing the foil between two plates of perforated steatite so as to inclose the portion to be heated in a steatite cell. It was found, however, that the close contact of the steatite conducted the heat away from the platinum so rapidly that only an irregular portion in the middle of the cell was actually fused, and the results were even more unsatisfactory than before.

It was next considered desirable to vary the method by heating a thick rod of platinum to its melting-point and allowing the light from the fused bead of metal thus obtained to pass to the photometer disc through a small opening in a suitable mask. This method was found to be all but impracticable, but it gave results of value as indicating one cause of the uncertainty in the quantity of light emitted from molten metallic surfaces. It was observed that small scum-like particles were constantly floating over the surface of the molten platinum, and that these particles gave far more light than the mass of metal itself. Consequently as there existed no means of ensuring the absence of such particles, it was obvious that there could be little certainty in the light emitted from such unevenly illuminated surfaces.

In addition to the blowpipe experiments, it appeared desirable to try the experiment of fusing platinum by means of the electric current as it seemed probable that by this means the platinum could be kept in any given condition of incandescence for a longer period, and that the experiment would be more under control. An apparatus for the purpose was consequently arranged. A strip of platinum was held between two metal clips insulated from each other. Close in front of the platinum was placed a small screen having a perforation of a quarter of an inch in

diameter through which the incandescent surface could be observed. This arrangement was placed in circuit with eight or ten cells of a secondary battery, an ammeter and an adjustable resistance being included in the circuit. It was necessary that the resistance should be capable of being taken out very slowly, so that the current might be gradually and regularly increased.

The arrangement devised answered very well in practice. It consisted of a frame across which was stretched a series of lengths of german-silver wire, some of them being straight and others coiled so as to give varying amounts of resistance in each length. By means of plugs any or all of the lengths could be put in and out at pleasure, and by this means the resistance could be roughly adjusted. The fine adjustment was given by a cross-piece working along two of the straight wires and moved by a moderately fine screw. As the cross-pieces moved along the length of the wires it, by connecting the two, brought more or less resistance into the circuit. The resistance of the whole arrangement amounted to about one ohm. It was found that with this arrangement the strip of platinum could be rapidly raised to incandescence, and could be kept close to the melting-point for a considerable time, a very slight increase in the current being then sufficient to cause fusion. The photometric tests made with this arrangement confirmed those which had been made when the platinum was fused by the oxyhydrogen jet; that is to say, the observations showed considerable irregularity, so much indeed that it did not seem worth while to make, as had originally been intended, a long series of them, nor to construct apparatus more accurate than the first experimental one.

A decided defect in the apparatus was the buckling of the platinum. As it was tightly gripped at each end there was no room for expansion, and before melting there was considerable expansion and consequent buckling. Had it seemed worth while to do so, it would not have been difficult to devise an apparatus by which this might have been obviated, but the results were not sufficiently encouraging.

A few photographic tests were also made by permitting the light from the incandescent platinum to fall through a screen with openings in it upon a sensitive plate, a number of exposures from different pieces of platinum being made on the same plate. These of course could only be looked upon as rough tests, but they also seemed to indicate that the amount of radiation from a given surface of platinum at the moment of fusion is not absolutely constant under the conditions we have described, and so far as they are worth anything they may be taken as confirming the conclusion obtained by the other methods.

Report of the Committee, consisting of Professor CRUM BROWN (Secretary), Mr. MILNE-HOME, Dr. JOHN MURRAY, Lord McLAREN, and Dr. BUCHAN, appointed for the purpose of co-operating with the Scottish Meteorological Society in making Meteorological Observations on Ben Nevis.

THE laborious work of observing hourly by night and by day has been carried on by Mr. Omond and his assistants during the past year with the same enthusiasm and continuity as in previous years; and the five daily observations at Fort William, in connection with the observatory, have similarly been made with the greatest regularity by Mr. Livingston.

The state of the health of the observers, occasioned by their continuous residence on the top of the mountain, where active exercise in the open air is practically precluded during most of the year, rendered it absolutely necessary to give them relief during last winter. Accordingly the services of Mr. Drysdale, B.Sc., were secured for six months, thus affording Messrs. Omond and Rankin three months' residence each in Edinburgh, during which they gave assistance in the office of the Scottish Meteorological Society. In this way effective help was given in the preparation of the report, for the 'Transactions of the Royal Society of Edinburgh,' of the Ben Nevis observations from the opening of the observatory in November 1883 to December 1887, to which date the report has been brought down. To these observations have been added the five daily observations made at the low-level station at Fort William. All of these observations are already printed, and as the report itself is now nearly all in type, the volume will shortly be ready for publication. The delay of publication has been occasioned by the extension of the period to December last and by a pressure of other work, which has precluded Mr. Buchan from giving more than a small portion of his time to the preparation of the report.

A grant of 25*l.* was obtained from the Government Research Fund in May last for the purchase of the necessary apparatus for photographing clouds and other meteorological phenomena at the observatory. Attention is meantime chiefly directed to clouds, halos, and other optical phenomena, and much interest is attached to the questions which have been already raised by these lines of research that give good promise of leading to a knowledge of the constituents of clouds, but more particularly of the exact forms of the ice-crystals of which many of them are composed.

During the year Mr. Omond has continued the observations on earth-currents, begun by Mr. H. N. Dickson in a previous year, and has traced an important connection between them and the general state of the weather. Mr. Rankin has collected the eighteen cases of St. Elmo's Fire which have occurred at the observatory and discussed the observations of pressure, temperature, winds, &c., for thirty hours previous and eighteen hours subsequent to their occurrence, together with the cyclones and other weather phenomena which, as shown by the daily weather-maps of the Meteorological Office, had occurred in North-western Europe at the times. The papers on these subjects will shortly appear in the 'Journal of the Scottish Meteorological Society.' As regards the cases
1888.

of St. Elmo's Fire it may be enough here to say that they occur at certain well-defined phases in the non-periodic fluctuations of atmospheric pressure, temperature, humidity, changes of wind, and arrival from the Atlantic of equally well-defined types of weather with their characteristic cyclones.

In addition to these researches and the preparation of the Ben Nevis observations for the press Messrs. Omond and Rankin have been conducting, as time and opportunity permitted, the investigations referred to in last year's report.

For the year 1887 the following were the monthly mean pressures and temperatures, the hours of sunshine, the amounts of the rainfall, and number of days without rain as recorded at the observatory, the mean pressures at Fort William being reduced to 32° and sea-level, those of Ben Nevis Observatory to 32° only:—

	Jan.	Feb.	March	April	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Year

<i>Hours of Sunshine to nearest Whole Hours at Ben Nevis Observatory.</i>													
No. of Hours	23	56	74	120	129	206	58	57	84	32	31	28	898
Possible Hours	231	264	365	426	508	529	528	467	381	319	242	210	4,470

For the year the mean temperature at Fort William was a degree below the average, the greatest defects from the means being 3°·0 in April, 2°·9 in December, 2°·7 in October, and 2°·3 in March. On the other hand, February was 1°·6 above the average temperature of the month, and June 2°·6. At the top of the Ben the mean temperature of June was even relatively higher than at Fort William, being 45°·4, which is the highest monthly mean hitherto observed.

The minimum temperature on Ben Nevis for the year was 9°·0 on March 12 at 2 A.M., which closely agrees with the minimum of previous years. The maximum was 67°·0 on June 24, which is 7°·0 higher than any previously recorded maximum. On seven days of this month the temperature rose above 60°·0, and on September 20 a temperature of 58°·8 was recorded. Indeed, an unusual occurrence of high temperatures was an outstanding feature of the meteorology of Ben Nevis during the year.

The registrations of the sunshine recorder showed 898 hours of sunshine during the year, the smallest number of hours, 23, occurred in

January, and the largest, 206, in June, the latter number being the largest for any month recorded down to the end of 1887. In June of 1888, however, there have been 250 hours' sunshine recorded, being nearly half the possible sunshine—an amount equalled at but few places in the British Islands last June. The hours of sunshine were 680 for 1885, 576 for 1886, and 898 for 1887, the amount of sunshine being thus greatly in excess of the two preceding years. In 1887 the amount was thus 20 per cent. of the possible sunshine, but in June the amount was 40 per cent. The distribution of the sunshine during the hours of the day from 6 A.M. to 6 P.M. was 29, 42, 62; 81, 90, 87; 88, 83, 76; 70, 51, and 46; a distribution closely agreeing with that of 1884, 1885, and 1886.

The amount of the rainfall for the year was 126·01 inches, the month of least rainfall, 3·97 inches, being May, and of greatest rainfall, 17·80 inches, January, the month of December, however, following close with a rainfall of 17·58 inches. The number of days on which the precipitation was *nil*, or less than 0·01 inch, was 128, being thus 31 dry days in excess of 1886. On the other hand the number of days on which one inch of rain, or upwards, fell were 37, or about one day in ten, being less frequent than in previous years, when such heavy rainfalls occurred once a week on the average. The unusually heavy rainfalls with the dates of their occurrence were 3·57 inches on January 27, 3·48 inches on December 3, 2·97 inches on December 4, 2·85 inches on February 23, 2·52 inches on the 24, and 2·47 inches on January 19. For longer periods the results are 7·19 inches for the four days ending January 28, 7·87 inches for the four days ending February 25, and 7·40 inches for the three days ending February 3.

Atmospheric pressure was considerably above the average for the year, the mean at Fort William being 29·934 inches instead of 29·834 inches. In November, December, and January it was considerably under the monthly means, but in every other month the means were exceeded, the greatest excess, 0·260 inch, being in June. Thus the June of 1887 is noteworthy in the meteorology of Ben Nevis for the prevalence of an unwonted high atmospheric pressure and for an equally unwonted high temperature, due to an unusual predominance of anticyclones over this part of Europe during at least the last two-thirds of the month, with the characteristic high temperatures and extremely dry states of the atmosphere which accompany them.

These warm, dry states of the atmosphere were most marked from the 22nd to the 25th. During these four days the means from the 24 hourly observations were :—

Day of Month	Dry	Wet	Pressure, Inches
22	58·2	50·6	25·943
23	59·3	48·0	25·912
24	60·7	49·9	25·931
25	58·3	50·3	25·865
Means	59·1	49·7	25·913
Means at Fort William	66·1	60·4	30·332
Differences	7·0	10·7	4·419

Thus, instead of the normal difference of $16^{\circ}0$ between the top and bottom of the mountain, it was only $7^{\circ}0$ during these four days, and, instead of the air at the top being moister than at the bottom, it was greatly drier. Hence the air at the top did not owe its great dryness and high temperature to ascending currents from lower levels up the sides of the mountain, heated by the strong insolation prevailing at the time, but to descending currents from great heights, which are characteristic of anticyclones, by which dryness and heat are developed much in the same way as happens in the case of the Föhn of the lower Alps. So markedly and so frequently did this type of weather prevail during June that the mean temperature of the month at the observatory was only $12^{\circ}9$ lower than that at Fort William, being the least monthly difference hitherto observed during any season of the year.

It may be here suggested that this peculiarity of anticyclones plays a highly important and beneficial part climatically in mitigating the rigours of winter over those portions of Asia and America which are almost continuously within extensive anticyclones during the winter months. For the investigation of this phase of weather and climate it is evident that the Ben Nevis observations afford data of the most invaluable description.

To this report is appended Table I., giving the hourly deviations from the mean atmospheric pressure for the months and the year, and Table II. the deviation from the mean temperature calculated from the four years' observations ending with 1887.

It was hoped that the work of discussing the Ben Nevis observations would by this time have extended farther than it has done beyond the determination of the hourly constants of the more prominent meteorological elements in the direction of the investigation of the relations of the observations to the weather of North-western Europe. But it was found that the preparation of the observations for the press, and seeing them through it, occupied much more time than had been anticipated. Indeed, this work occupied the whole time of Messrs. Omond and Rankin when they were in the office of the Scottish Meteorological Society, together with nearly the whole of the time of the treasurer's clerk; and, besides, since the beginning of the year less time has been at Mr. Buchan's disposal for personally carrying out the laborious work of the discussion.

In these circumstances the directors of the observatory have taken into consideration the whole question, and are maturing a plan for a thorough discussion of the Ben Nevis and Fort William observations in their scientific and practical bearings, which they hope to complete in the course of the autumn. This plan will require for the carrying of it out a small additional staff working in conjunction with the office in Edinburgh and the staff of the Ben Nevis Observatory for a period of at least three years.

In connection with the practical side of the inquiry your Committee refer with the greatest satisfaction to the publication by General Greely, chief signal officer of the United States Army, of Daily Weather Charts of the Atlantic, beginning with October 1886. These charts have been partially examined in connection with the Ben Nevis observations, and it is not possible to overestimate their importance in the large inquiry now in contemplation by the directors as to the relations of these observations to the weather of North-western Europe, which is truly an international undertaking. With the United States charts will be conjoined the obser-

vations of storms and other phenomena made at the Scottish lighthouses, as described in previous reports, and the bi-daily charts of the Meteorological Office. One of the points to which attention will be specially given will be to ascertain the earliest time at which storms, seen to be advancing over the Atlantic towards Europe, could be signalled from the Ben Nevis observations in combination with observations at lower levels; and, further, to endeavour from an investigation of the bearings of the Ben Nevis observations on the movements and courses of anticyclones and cyclones to ascertain the path the advancing cyclone will take, whether to the north of, across, or to the south of the British Islands in its easterly course.

As the British Association is aware, your Committee have from the commencement insisted on the necessity of an observatory at Fort William, near sea-level, at which hourly observations can be recorded, in order that the observations made at the top of Ben Nevis may be properly utilised in their scientific and practical bearings.

With reference to this low-level observatory a copy of the Report of the Council of the Scottish Meteorological Society, dated July 23, is sent herewith, with a passage marked on page 2 giving a correspondence with the Meteorological Council, who offer a grant towards the maintenance of the low-level observatory, 'which they regard as a very important adjunct to the existing high-level observatory,' and further to equip the observatory with the required outfit of meteorological instruments. The directors have applied to the Association of the Edinburgh International Exhibition of 1886 for a grant from their surplus fund towards the building of the observatory at Fort William, and they are in good hopes that they will in a month or two be in a position to commence the building.

TABLE I.—*Showing the Hourly Variations from the Mean Atmospheric Pressure (expressed in Thousandths of an Inch) from the four years' observations ending with 1887.*

Second Report of the Committee, consisting of Professors TILDEN, MCLEOD, PICKERING, RAMSAY, and YOUNG and Drs. A. R. LEEDS and NICOL (Secretary), appointed for the purpose of reporting on the Bibliography of Solution.

DURING the past year the following journals have been searched :—

- Poggendorff's ' Annalen ' (completed) ;
- ' Annales de Chimie et de Physique ' ;
- ' Chemical News ' ;
- ' Philosophical Magazine ' ;
- ' Philosophical Transactions ' ;
- ' Proceedings of the Royal Society of London ' (in part) ;

in all 350 volumes ; with the result that 194 papers have been added to the list. These papers are distributed as follows :—

A. 1=8 ; 2=4	12
B. 1=29 ; 2=1 ; 3=2	32
C. 1=21 ; 3=6 ; 4=17 ; 5=10 ; 6=13 ; 7=5 ; 8=1 ; 10=1	74
D. 1=15 ; 2=2	17
Miscellaneous	59

The number of papers obtained in all is 549.

The Committee is indebted to Mr. T. J. Baker, B.Sc., King Edward's School, Birmingham, for assistance in searching the ' Annales de Chimie et de Physique.'

Report of the Committee, consisting of Professor G. CAREY FOSTER, Sir WILLIAM THOMSON, Professor AYRTON, Professor J. PERRY, Professor W. G. ADAMS, Lord RAYLEIGH, Dr. O. J. LODGE, Dr. JOHN HOPKINSON, Dr. A. MUIRHEAD, Mr. W. H. PREECE, Mr. HERBERT TAYLOR, Professor EVERETT, Professor SCHUSTER, Dr. J. A. FLEMING, Professor G. F. FITZGERALD, Mr. R. T. GLAZEBROOK (Secretary), Professor CHRYSTAL, Mr. H. TOMLINSON, Professor W. GARNETT, Professor J. J. THOMSON, Mr. W. N. SHAW, Mr. J. T. BOTTOMLEY, and Mr. T. GRAY, appointed for the purpose of constructing and issuing Practical Standards for use in Electrical Measurements.

[PLATE I.]

THE Committee report that the work of testing resistance coils has been continued at the Cavendish Laboratory, and a table of the values found for the various coils is given.

Legal Ohms.

No. of Coil	Resistance in Legal Ohms	Temperature
Elliott, 193  No. 178	·99971	15°·5
Elliott, 201  No. 181	1·00005	14°·8

B.A. Units.

No. of Coil	Resistance in B.A. Units	Temperature
Elliott, 200  No. 71	1·00049	13°·8
Elliott, 43  No. 72	·99955	14°·7

In conformity with the opinion expressed by the Committee in their last report some steps have been taken towards the construction of an air-condenser.

A meeting was held in London and Dr. Alex. Muirhead exhibited an air-condenser, capacity about ·0035 mf. This condenser consists of a series of concentric cylinders of brass insulated from each other by glass rods.

Dr. Muirhead expressed his willingness to lend this condenser to the Committee with two others of similar construction, and it was agreed that the Secretary should be requested to test them and to make a determination of their absolute capacity. Some delay in sending the instruments to Cambridge unavoidably took place, but the experiments requisite are now in progress; so far, of the 80*l.* granted last year for the purpose only 2*l.* 10*s.* has been expended.

During the year the original resistance standards of the Association

have been compared with each other by the Secretary and Mr. T. C. Fitzpatrick; an account of the experiments is given in an appendix to the report, together with a chart giving the values of their resistance between 10° and 20° . The general result of the comparison is that with two exceptions the relative values of the standards between the temperatures of 10° and 20° have not seriously changed since they were constructed in 1865 until June 1888. A change of about $\cdot 0002$ B.A. Unit has been observed in the coil F since the end of June 1888.

The attention of the Committee has been directed by several practical electricians to the desirability of a redetermination of the value of the specific resistance of copper. It is known that copper wire is now made having a resistance 3 or 4 per cent. less than Matthiessen's standard.

In view of the importance of copper to electricians the Committee have undertaken to make experiments on the specific resistance of copper, and wish to thank the various gentlemen, who have brought the matter forward, for their offers of help.

At the last meeting of the Committee it was resolved, on the motion of Mr. W. H. Preece, to adopt the name 'Therm' for the Gramme-Water Degree Centigrade Unit of Heat.

Thus one 'Therm' is the quantity of heat required to raise one gramme of water at its maximum density one degree Centigrade.

It was also agreed to adopt the name 'Joule' for 10^7 C.G.S. units of work. Thus a Joule is equal to 10^7 ergs. It is the work done in one second by the power of one Watt, or again the work done when a current of one Ampère flows for one second between two points between which the difference of potential is one Volt, and hence a power of one Watt is one Joule per second.

Hence, also, if we take the value of the mechanical equivalent of heat as $4\cdot 2 \times 10^7$ ergs, we have

$$1 \text{ Therm} = 4\cdot 2 \text{ Joules.}$$

In accordance with a suggestion made at the Manchester meeting the value of the resistance of mercury in terms of the B.A. Unit has been again determined by the Secretary and Mr. Fitzpatrick.¹

They find that a column of mercury 1 metre long 1 sq. mm. in section has at 0° C. a resistance of $\cdot 95352$ B.A. Unit, and that the value of the ohm in centimetres of mercury is $106\cdot 29$.

The Committee are of opinion that they should be reappointed, with the addition of the name of Mr. T. C. Fitzpatrick, to continue the experiments already referred to; they ask for a grant of 100*l*. They propose that Professor G. Carey Foster should be the Chairman and Mr. R. T. Glazebrook the Secretary.

APPENDIX.

On the Permanence of the Original Standards of Resistance of the British Association and of other Standard Coils. By R. T. GLAZEBROOK and T. C. FITZPATRICK.

The original standards were compared together by Messrs. Matthiessen and Hockin in 1865 and 1867, by Messrs. Chrystal and Saunder in 1876, by Dr. Fleming in 1879–81, and by the Secretary and Mr. Fitzpatrick in 1887–88. The details of Dr. Fleming's observations have never been

¹ *Proc. Royal Soc.* vol. xliv.; *Phil. Trans.* 1888.

published, and we have to thank him for having placed his note-book and papers at our disposal. ••

The question of the permanence of wire standards has been discussed recently by Professor Himstedt, 'Wied. Ann.' xxxi. p. 617, and it seemed desirable to bring together all the information attainable as to the original coils of the Association and others used by Messrs. Matthiessen and Hockin in 1867.

The original coils of the Association are six in number, and the temperatures at which each has a resistance of 1 B.A.U. are given by Mr. Hockin in the Report for 1867. In addition to these six coils Messrs. Chrystal and Saunder examined the coil No. 29, marked F by them, and also a coil known as Flat, which are not mentioned in Mr. Hockin's report. The results of these two comparisons are given in the following table:—

TABLE I.—Table giving the results of comparisons in 1867 and 1876.

Material of Coil	No. in 1867 Report	Mark in 1876 Report	Temperature at which Coil is 1 B.A.U., 1867	Temperature at which Coil is 1 B.A.U., 1876 ¹
Pt Ir	2	A	16°	16·1
Pt Ir	3	B	15·8	15·8
Au Ag	58	C	15·3	15·3
Pt	35	D	15·7	16
Pt	36	E	15·7	15·8
Pt Ag	29	F	not given	(19·4?)
Pt Ag	43	G	15·2	18·2

It will be noticed that the coil G of Pt Ag is the only one for which the table shows any marked alteration.

Now Matthiessen gives as the percentage increase of resistance per 1° C. for Pt Ir the value ·032. Our own experiments show it to be lower than this, and the value found for G by Dr. Fleming after a most careful series of experiments is ·0278. I can find no record of the temperature at which Hockin actually worked. If it were below 15° and the temperature at which the coil was right was found by the use of the coefficient ·032 the temperature so found would be too low.

If we assume Hockin's measurements to have been made at 0° C. and take Fleming's value ·028 for the coefficient we find the temperature at which the coil was right to be 18°·1.

We have next to consider the very complete series of measurements taken by Dr. J. A. Fleming in 1879–81; the results of these measurements were tabulated on a chart which has been kept with these coils since that date. For the details of the experiments we have to thank Dr. Fleming, who placed at our disposal his note-books. The principle of his observations was as follows. If X, Y be two coils to be compared, one X, say, was kept at 0° C., while the temperature of Y was varied from 0° to 20°. The differences between the resistance of X at 0° and Y at various temperatures were measured by Carey Foster's method in terms of the wire of the Fleming bridge. The values of this difference were plotted as ordinates, the temperatures being the abscissæ, and thus a curve was obtained giving the variation of resistance with temperature

¹ In obtaining this column it was assumed that B remained unchanged between 1867 and 1876.

for the coil Y. For the standard coil Flat this curve is accurately a straight line. This coil was then kept at 0° , and the temperature of X varied, and so on for all the coils.

Now, at the temperatures given in Table I., column 4, taken from the 1867 Report the resistances of all the coils should be the same. Fleming found that this was not quite strictly true. He defines therefore as the Mean B.A. Unit the mean of the values of the coils at the temperatures at which they were originally said to be equal. This value is shown on his diagram by a red horizontal line.

For the coils of platinum silver alloy, which is now used for standards, Fleming's results are accurately represented by straight lines for the temperature curves. This, however, is not so strictly the case for the coils A and B of platinum iridium alloy; thus for these two coils Fleming took observations in the neighbourhood of 0° , 4° , 8° , 15° , and 21° , numerous observations being made at each temperature; the straight line on the chart joining the means of the observations at 15° and 21° passes considerably above the observations at 0° , 4° , and 8° . The same too is the case, though in a less marked degree, for the platinum coils D and E. In the chart as drawn by Fleming it has been assumed that the temperature curves are straight lines, and these have been drawn to represent all the observations as closely as possible, but the differences are considerable.

If we draw curves instead of straight lines to represent Fleming's experiments these curves between 10° and 20° are in all cases nearly straight, and the differences, at the two temperatures, from Flat at 0° are given in bridge wire divisions in Table II.

TABLE II.

—	Temperature 10°	Temperature 20°
A	-88	205
B	-97	196
C	11	155
D	-280	338
E	-263	348
F	44	100
G	40	94
Flat	56	112

We could determine from this table the temperatures at which the various coils are equal, and hence compare Fleming's results with those of previous observers; it will be easier to do this after discussing our own observations.

During the past year and a half the coils have again been examined by ourselves. We find that between the temperatures of about 10° and 20° Centigrade the resistances of the coils, including an eighth coil H (No. 6 of the Report of 1867), may be represented by the formulæ given in Table III.

In obtaining the table it has been assumed, in accordance with the observations of Dr. Fleming, confirmed by Lord Rayleigh and ourselves, that the resistance of one division (about 1 mm.) of our bridge wire at a temperature of 15° is .0000498 B.A.U. The table gives in B.A. Units the value of $R_t - \text{Flat}_0$, R_t being the resistance of the coils in order at temperature t° , Flat_0 that of Flat at 0° .

TABLE III.

Coil	$R_t - \text{Flat}_0$ in B.A.U.
A	$- \cdot 00386 + \cdot 001426 (t-10)$
B	$- \cdot 00431 + \cdot 001436 (t-10)$
C	$+ \cdot 00057 + \cdot 000710 (t-10)$
D	$- \cdot 01434 + \cdot 003078 (t-10)$
E	$- \cdot 01330 + \cdot 003023 (t-10)$
F	$+ \cdot 00227 + \cdot 000286 (t-10)$
G	$+ \cdot 00192 + \cdot 000274 (t-10)$
H	$+ \cdot 00202 + \cdot 000281 (t-10)$
Flat	$+ \cdot 00279 + \cdot 000279 (t-10)$

The results of these observations are given in the chart,¹ Plate I.

The vertical divisions are ten bridge divisions, and the horizontal divisions $0^{\circ}2C$. In the original chart, which is retained with the standards, the vertical divisions were one bridge division, or $\cdot 0000498$ B.A.U.

About eleven observations on each coil are recorded in the chart, and in but few cases is the error between observation and the corresponding straight line greater than that which would arise from an error of one-tenth of a degree Centigrade in the temperature of the coil.

If as above we adopt as the Mean B.A. Unit the mean of the value of the coils at the temperature at which each was said to be originally correct we find that this mean lies on our chart at a distance of $78\cdot3$ divisions above the value of Flat at 0° , so that

$\text{Flat at } 0^{\circ} = 1 - \cdot 00390 \text{ B.A.U.}$

The value given on Fleming's chart is Flat at $0^{\circ} = 1 - \cdot 00410$ B.A.U., and the difference is within the errors of reading on his chart.

We have thus the data for finding the resistance of any of the coils in Mean B.A.U. at any temperature between 10° and 20° .

It remains to compare these results and those of previous observers. We will take Fleming's observations first, and for this purpose have given in Table IV. the differences in bridge wire divisions between the coils at temperatures of 10° and 20° and Flat at 0° . For the sake of comparison Table II. is repeated.

TABLE IV.

Coil	Value of $R - \text{Flat}_0$ at 10°		Value of $R - \text{Flat}_0$ at 20°	
	1880	1888	1880	1888
A	-88	-77.5	205	209
B	-97	-86.5	196	202
C	11	11.5	155	154
D	-280	-288	338	330
E	-263	-267	348	340
F	44	45.5	100	103
G	40	38.5	94	93.5
H	—	40.5	—	97
Flat	56	56	112	112

¹ Note.—The smaller letters in brackets after some of the observations on the chart give the initials of the observer.

A comparison of the corresponding columns shows that the differences, except possibly in the case of A and B at the lower temperature, are probably not greater than the error of experiment. It must be remembered that A and B change by 28 bridge divisions for 1° Centigrade, while for D and E the change is about 60 divisions per degree; the temperature of the coils is hardly certain to 0°·1 Centigrade and the differences are within that error. As to the platinum silver coils it would seem possible that F¹ has risen relatively to Flat by ·0001 B.A.U. and that G has fallen by ·00005; but these differences are almost too small to make certain of. With regard to the results for A and B at 10° it may be remarked that Fleming's line for these coils is more curved than for any of the others, and that his observations at 6°·9 and at 3° lie distinctly above the line which seems to represent best the observations at 0°, 9°, 15°, and higher temperatures. The observations are not at sufficiently close intervals of temperature to enable the curved line to be drawn with accuracy, and it is clear when plotting them that the curve near 10° may be wrong by as much as 5 or 6 bridge wire divisions.

We would conclude then that there is no certain evidence for a change in the coils in the interval 1880 to 1888. A comparison with the results of Hockin and Chrystal is not quite so easy. It is clear from the chart that the coils are not exactly equal at the temperatures originally stated, and any table of temperatures at which they may be said to have the value of 1 B.A. Unit will depend on the assumption made as to possible changes in any of the coils. Chrystal in 1876 found that the coils B and C were equal at the temperatures at which they were originally stated to be each 1 B.A. Unit. He supposed these coils had not altered and founds on that assumption a table of standard temperatures which agrees well with that of Hockin except for the coil G. According to our observations the coils now marked as B and C are no longer equal at the temperatures mentioned. We find, however, that D, E, and G are practically equal at the temperatures given by Chrystal, and if we suppose G has not altered we get the following table of standard temperatures:—

TABLE V.

Coil	Standard Temperature, 1876	Standard Temperature, 1888
A	16·1	15·7
B	15·8	16
C	15·3	15·1
D	16	16
E	15·8	15·8
F	19·4?	16·9
G	18·4	18·4
H	—	17·9
Flat	—	15·2

The change in C, as shown in this table, is not large, probably hardly greater than would be accounted for by experimental error, while D, E, and G agree very closely.

The differences in the case of A, B, and F are important. To take F first. It is a platinum silver coil, No. 29 of the original report. Its

¹ The results of other experiments confirm this rise in the value of F.

temperature is, however, not given in the Report for 1867, p. 483, nor is it marked out in coil itself. Chrystal says that it was used in some of the experiments 'because its variation coefficient was small, but otherwise we have not bestowed much attention on it.' In his first table he states that the results given for F came from a single experiment, and he gives as its variation coefficient per 1° Centigrade 28 divisions of his bridge, while Flat and G, also platinum silver coils, have coefficients of 34 and 35 divisions. Now the observations of Fleming and ourselves show that without any doubt these coils Flat, F, and G have practically the same coefficient, viz., $\cdot 00028$ B.A.U. per 1° C. Taking Chrystal's bridge wire as $\cdot 075$ ohm as stated by him, his value for Flat and G comes to $\cdot 00026$ B.A.U., which is in fair agreement; while for F we find $\cdot 00021$, a value which is now undoubtedly too low. We must infer either that the value of F has changed considerably or that there is some accidental error in the one observation given in Chrystal's table. The change necessary to account for the temperature difference recorded in Table V. would be an increase in resistance of $\cdot 00067$ B.A.U.

Let us now examine the numbers for A and B. It will be seen at once that they have altered appreciably, having, in fact, just changed places. Their temperature coefficients are nearly the same, and there is no doubt that throughout Chrystal's observations the coil he called B was slightly higher in value than A, while throughout the observations of Fleming and ourselves the reverse has been the case. The question naturally arises, have the coils been interchanged? Chrystal (Report, 1876, p. 17) states that, though they have no proper labels, they are marked in some way or other so as to be identifiable. At the present time they have brass labels screwed on to the ebonite of the frame bearing the stamp B.A. 76 A and B.A. 76 B respectively. These were placed on at the time of Chrystal's observations, and there seems just the possibility of an accidental interchange.

The coil H, No. 6, of the original report is marked as correct at $15^{\circ} \cdot 3$. It is now correct in the sense used above at $17^{\circ} \cdot 9$, and here again we have apparently a large change. The resistance would appear to have gone down by about $\cdot 00070$ B.A.U. in the twenty-two years which have elapsed since it was made. This corresponds closely to the change in G observed by Chrystal between 1867 and 1876. Now we know that G has not changed relatively to C, D, and E, since 1876—unfortunately H was not examined by Chrystal—and we are led to ask whether the change was a real one, or due in some way to the observations. The suggestion already made in case of G applies again. The temperature coefficient used by Matthiessen and Hockin is certainly too high, $\cdot 00032$ instead of $\cdot 00028$. If his observations on the platinum silver coils were made at low temperatures, and then the value of the temperature at which the coil is correct were found by the use of the temperature coefficient, the result would be too low. It will be seen shortly that all the platinum silver coils examined, not merely those already mentioned, appear to have fallen appreciably in value relative to the others.

But we have another method of comparing the results. Chrystal has given a table of the differences at 10° between each of the coils and Flat. Now we have seen reason to believe that there is not much change in C, D, E, and G. Let us find from Chrystal's table the value of the difference between G and the various coils at 10° , and compare these with our results. In doing this some uncertainty is introduced from the fact that the value

of the bridge wire in Chrystal's observations (was only determined approximately as .075 B.A.U. In this way we get the following Table VI.

TABLE VI.

<i>x</i>	Value of G—X at 10° in B.A.U.		Difference
	1876	1888	
A	.00693	.00583	.00110
B	.00648	.00635	.00013
C	.00162	.00135	.00027
D	.01596	.01632	— .00036
E	.01506	.01527	— .00021
F	— .00018	— .00035	.00017

On examining these differences it would seem that A has changed greatly, while B has remained unaltered. This is not in accordance with the conclusions derived from Table V., and will require further consideration. With regard to the other four coils, the differences are almost within errors of observation and are in fair agreement with Table V. Coil C appears to have risen relative to G by .00027; thus, since its temperature coefficient is .00071, this would correspond to an apparent fall in the temperature at which it is right of about 0°·3 Centigrade. Table V. shows that there has been a fall in this temperature of 0°·2.

The temperature coefficients of D and E are about .00308, so that the differences recorded for these coils would be accounted for by an error of 0·1 in the temperature, while the change in F relative to G is so small as to be within the experimental errors. We are thus led to infer that, while C may have risen slightly, the others have not changed by any but a very small amount. This conclusion as regards F is at variance with the one derived from Table V. In fact, while at 10° F is above G in value; owing to the small temperature coefficient used by Chrystal for F, its curve of resistance crosses that of G, and at temperatures near 18°, at which G is about right, F is considerably below it.

If we take Chrystal's value for F at 10° and the temperature coefficient .00026 instead of .00021 used by him, we find that F would be right at about 17°·6 instead of at 19°·4, as given by Chrystal. This is much closer to 16°·9, the value given by our observations; if we take it instead of the 19·4 of Table I., the results of this Table VI. and of Table V. would point to a rise in the value of F of about .00017.

The conclusion then that would seem to follow from a comparison of these two series of observations in 1876 and 1888 would seem to be that, while considerable uncertainty attaches to the coils A and B, changes in the other five coils, C, D, E, F, and G, if they have occurred at all, are probably not so great as .0002 B.A. Unit. C and F may possibly have risen by this amount, while D, E, and G have not varied at all.

Professor Chrystal's observations in 1876 are in accordance with those of Messrs. Matthiessen and Hockin in 1864 and 1867, while the results of Dr. Fleming's work in 1880 agree, as we have seen, with our own at the present date.

The observations recorded and discussed above were made mostly at temperatures between 10° and 20°. A considerable number more were made during the cold weather in January and February of the present year at temperatures near 0°, and we must now consider them.

At these low temperatures the observations are not nearly so concordant as those already considered. The terminals of the coils are stout rods of copper, and whenever the temperature of the room is different from that of the bath in which the coils are placed heat is conducted to them through the copper rods and the temperature becomes uncertain; besides this it is difficult to prevent the deposition of moisture on the paraffin with which the cases are filled, and this again becomes a source of error. Table VII. gives a series of the differences observed between the various coils and Flat. The coils were in a north room of which the windows were open, and the temperature in the room was on the average about 2°C . The differences are given in bridge wire divisions.

TABLE VII.

Coil	Feb. 2, Morning	Feb. 22, Afternoon	Feb. 23	Feb. 24, Afternoon	Feb. 25, Morning	Feb. 25, Afternoon	March	Mean
A	433.9	422.4	424.4	428	422.7	422.6	—	425.9
B	459.9	452.4	454.7	455.8	452.0	—	451.5	454.7
C	136	—	—	—	—	134.6	135.5	134.3
D	913.8	922.4	—	927.4	921.0	—	—	921.7
E	894.2	895.4	—	905.8	907.0	—	—	901.1
F	6.4	5.4	5.3	7.5	7.8	9.6	9	7.3
G	14.1	16.8	—	16.8	16.7	18.4	18	16.5
H	15.7	15.7	16	16.7	15.4	17	16	16.1

Now from Tables III. or IV. we can easily calculate what these differences ought to be if we suppose that the temperature curves are straight lines. In making a comparison of the results of this calculation with the observed values given in Table VII. some allowance must be made for the fact that the bridge wire referred to in IV. was at a mean temperature of about 15° , while in Table VII. the temperature was about 2° . Now the temperature coefficient of the bridge wire—platinum iridium—is about .00143; thus the change in resistance for 13° of temperature will be .0185 of the resistance at 2° , and we shall have to reduce each of our observed values by this fraction of itself.

We thus get the following Table VIII. of values of the difference at 0° between Flat and the various coils.

TABLE VIII.

Coil	Observed Value of Flat—X corrected for temperature of bridge	Value of Flat—X at 0° obtained from Table III.	Difference
A	417.7	364	53.7
B	446.1	375	71.1
C	131.8	131	0.8
D	904.2	906	— 1.8
E	884.0	874	— 10
F	7.2	12	— 4.8
G	16.2	16.5	— 0.3
H	15.8	16	0.2

On examining these it is at once clear that the supposition that the temperature curves for A and B are straight lines is false.

The other coils, with perhaps the exception of F, would lie at 0° on the straight line which represents the observations between 10° and 20° within the limits of the errors of experiments.

The numbers given in Table VIII. agree well with those found by Fleming in 1880 with the exception of the coils A and B.

Some observations made at intermediate temperatures are in agreement with the statements just made. Thus on March 2, the temperature of the room being 12°, we found that at 4°·9 C. the difference between A and Flat at 0 was 256 bridge wire divisions, while for B at 4°·8 the difference was 280 bridge wire divisions.

Thus in conclusion we infer that while the observations in 1880 and 1888 are in close accord for temperatures between 10° and 20° there is a discrepancy between them at lower temperatures for the two coils of platinum iridium A and B. The other coils, however, do not show any marked evidence of change. For the same two coils there is a discrepancy between our results and those of Chrystal in 1876 and Hockin in 1867. For the other coils the agreement between Chrystal and ourselves is as close as can well be expected, and our results as well as those of Chrystal agree with Hockin's for the gold silver coil C and the platinum coils D and E. According to both Chrystal and ourselves the platinum silver coils have fallen in value relatively to the others by something like ·0006 B.A.U., corresponding to change in the temperature at which they are correct of some 2° Centigrade. We have seen, however, that G, the only one of these coils which was carefully examined by Chrystal in 1876, has not altered since. In its case the whole fall, if it occurred at all, took place between 1867 and 1876, and we suggest that possibly the fall has not been a real one, but merely apparent, owing to the use of the wrong temperature coefficient by Hockin.

TABLE IX.—*Giving the Values in 1888.*

Coil	Original No. See Report, 1867	Material	Temperature at which coil is cor- rect, 1867	Value of coil in Mean B.A. Units at the temperature given in 1867	Temperature at which coil is 1 B.A. Units, 1888	Temperature Coefficient in B.A. Units
A	2	Pt Ir	16°	1·00075	15°·4	·00143
B	3	Pt Ir	15·8	1·00010	15·7	·00144
C	58	Au Ag	15·3	1·00050	14·8	·00071
D	35	Pt	15·7	·99930	15·9	·00308
E	36	Pt	15·7	1·00000	15·7	·00302
F	29	Pt Ag	—	—	15·7	·00028
G	43	Pt Ag	15·2	·99940	17·3	·00028
H	6 ¹	Pt Ag	15·3	—	16·8	·00028
Flat		Pt Ag	—	—	14·0	·00028

As has been said already, the value that has been assumed as the Mean B.A. Unit since Fleming constructed his chart in 1876 is the mean of the values of the six coils A, B, C, D, E, and G mentioned in the Report for 1867 at the temperatures at which they were then said to be

¹ This coil is not mentioned in the Report of 1867. The details given are from the label.

correct. In terms of this unit we find, Table IX., the present values at the temperatures of 1867. We also give in the last column but one the temperatures at which these coils have the value 1 B.A. Unit, and in the final column the temperature coefficients per 1° Centigrade also in B.A. Units.

There remains now for consideration the result of comparisons which we have made on various other standard coils originally issued by the Committee, and which have most kindly been put at our disposal by their owners for the purposes of the report.

Messrs. Elliott Bros. have three coils. One, No. 41 of the original set, was made by Matthiessen in 1864. A second, No. 56, was first examined by Lord Rayleigh in 1882: these two are B.A. Units, while the third, Elliott, No. 117, is a legal ohm, first tested by R.T.G. in 1884. These coils are all of platinum silver, with a temperature coefficient of .00028. Table X. gives the temperatures at which they were found correct at different dates.

TABLE X.

Coil and Mark on it at present	Matthiessen, 1864	Hockin, 1879	Hockin, 1880	Lord Rayleigh, 1882	Glazebrook, 1884	Glazebrook, 1885	Glazebrook, 1887
No. 41  No. 55	15.2	13.2	14.2	14.5	15.5	15	6.2
No. 56  No. 56	—	—	—	14.1	15.4	—	14.7
No. 117  No. 63	—	—	—	—	17.8	—	16.8

The observations made in 1887 are separated from the others by a double line because during 1886 it was observed that the paraffin used in the insulation was becoming green, and it was therefore removed and replaced by pure ozokerit. In consequence of this some change may easily have taken place in the coils, and the record after 1884 must be treated as a fresh one.

In the first coil the most noticeable point is the drop of 2° between 1864 and 1879; but since this drop is followed by a rise of 1° in the next twelve months one may feel uncertain as to whether it is real or due to some error in 1879.

In the next five years there appears to be a gradual rise in temperature corresponding to a fall in resistance; the total amount would correspond to a change in resistance of about .0004 B.A. Unit. The removal of the paraffin has seriously affected No. 41.

The next coil also of platinum silver, is one belonging to Professor Carey Foster. He writes as follows:—‘It professed to be equal to

1 B.A. Unit at 14°·2 C.

I had it direct from Matthiessen, who, I believe, adjusted it specially for me from his standards.’ On comparing it with F in May 1887 we find that it has a resistance of .99983 Mean B.A. Unit at 16°·2. It would therefore be right at 16·8.

This, of course, shows a considerable change, corresponding apparently to a fall in its resistance of about .00073 B.A. Unit. It will be noticed 1888.

that this fall is just about the same as that observed in the platinum silver units of this Committee—F, G, and H. We shall refer to it again in connection with the next series of observations.

But by far the most important series of coils are a set belonging to Mr. H. A. Taylor. With regard to them he writes :—‘ Most of my coils belonged to Hockin long before I knew him, and at his death they were given to me by his father.’ ‘ The early history of these coils is lost, unless it can be found in Matthiessen’s note-books. I am informed, however, that the one unit coil I sent you both last year and this, Φ No. 68, was copied by Hockin from the B.A. coils you now have at Cambridge at the time when he had regular access to them. Whether from a particular standard or from the mean of several, I do not know ; but he considered it to be at 15°·5 C. less than B.A. Unit by ·0003. I presume the Au Ag coils, Nos. 19 and 34, were verified by Matthiessen and Hockin, as they have the formal B.A. stamp. With regard to the tens, one, I think, belonged to Hockin and the other was purchased by Messrs. H. C. Forde and Fleming Jenkin of the Committee in the usual manner.’

Table XI. gives Mr. H. A. Taylor’s observations on his coils on the assumption that Hockin’s standard has not changed.

TABLE XI.—Assuming a Coil (Hockin’s Standard) tested by Electrical Standards Committee (Φ No. 68) to be, as stated by Hockin, smaller than 1 B.A. Unit by $3^{\circ}/_{\infty}$ (three-hundredths per cent.) at 15°·5 C. The Table shows the Resistance in terms of 1 B.A. Unit of other Standards 15°·5 C. at the dates given.

	Material	Temperature Coefficient $^{\circ}/_{\infty}$	December 1874. Observations at 15°·5 C.	January 1875. Observations at 17°·3 C.	May 1879. Observations at 15°·5 C.	September 1879. Observations at 16°·6 C.	June 1887. Observations at 16°·1 C.	May 1888. Observations at 16°·47 C.
1 (C. F. T.) copy called right at 16°·1 Centigrade	Pt Ag	2·6	·99994	·99997	·99985	·99984	·99985	—
1 (No. 19) B.A. coil issued as right at 15°·5 C.	Au Ag	6·5	—	·99969	·99980	·99979	·99963	—
1 (No. 34) B.A. coil issued as right at 15° 8 C.	Au Ag	6·9	1·00007	1·00014	1·00023	1·00023	1·00018	1·00020
10 (C. F. T.) copy called right at 15°·6 C.	Pt Ag	2·6	—	10·0001	9·9992	9·9991	9·9991	—
10 (No. 3) B.A. coil issued as right at (?)	Pt Ag	3·1	10·0008	10·0021	10·0013	10·0013	10·0012	10·0011
10 (No. 4) B.A. coil issued as right at 16°·0 C.	Pt Ag	3·1	10·0009	—	9·9995	9·9999	9·9997	9·9991

Where the temperature of observation differs from 15°·5 C. the reductions to that temperature are made by the temperature coefficients given.

The evidence of a change is very small. The observations have lasted over 14 years. For the first coil there would seem possibly to have been a drop of about ·0001 between 1875 and 1879. The next coil may have risen by as much and fallen again, while the third coil would seem to have risen by ·00015. The results for the ten ohm coils are much the same. From the six coils, some of platinum silver, some of gold silver, we conclude that there is certain evidence no change greater than 1 in 10,000 has occurred in the last fourteen years.

The next table enables us to compare these coils with the standards at

Cambridge. It will be noticed at once that relatively to the Cambridge standards the coils have all fallen.

TABLE XII.

Coils	Col. I.	Col. II.	Cl. III.	Cl. IV.	Col. V.	Col. VI.

		(1887)				
10 No. 3 =  69	10·00000 at 15·5	10·00209 at 18·1	Assumed 3·1		9·99403	

Let us take first Hockin's standard  68. Using Taylor's temperature coefficient we find as its present value—the mean of the two given in the last column—at 15°·5, ·99901. It has therefore fallen relatively to the Mean B.A. Unit by ·00069, practically the same fall as that found for all the other platinum silver coils examined. The coil C.F.T. (the first coil in Table XI.) will also clearly have fallen by the same amount. Similarly with the ten unit platinum silver coil  69; it has fallen from 10 to 9·9940, or by ·006, nearly the same percentage; and since, according to Table XI., the coils have not changed relatively to each other and to the gold silver coils by more than one-sixth of this amount since 1874, there is some probability that the change, if it has taken place at all, occurred between 1867 and 1874. It will be remembered that we arrived at a similar conclusion with regard to G. The difference between the values of  68, found by myself in 1887 and 1882 as recorded in the two last lines of Table XII., arises from the fact that in 1887 the coil was compared with F, and in 1888 with Flat and G. In making the calculation it was assumed that the values of F, Flat, and G in terms of the Mean B.A. Unit had remained unchanged since Fleming's time. The results of our comparisons given in Tables IV., V., &c., would, as has been said, point to a slight rise in F of possibly as much as ·0001, and this would reconcile the two values for 1 H or  68. As regards the gold silver coils Nos. 19 and 34, if we take the value as issued, the one has fallen by ·00111, the other by ·00037. We must remember that the temperature coefficients for these coils are much greater than for the platinum silver coils.

If, however, we compare the values as issued with those found by Taylor in 1875—Table XI., column five—we find that while No. 19 was

then $\cdot 99969$ at $15\cdot 5$, showing a fall of $\cdot 00031$. No. 34 was $1\cdot 00014$, showing a rise of $\cdot 00014$. Since this date No. 19 has fallen therefore by $\cdot 0008$, and No. 34 by $\cdot 00051$, and these numbers are within the limits of error of the fall of $\cdot 00065$ found for the platinum silver coils. We would infer then that while apparently there was a serious change in these coils relatively to the platinum silver standards between the date of issue and 1875, since that date there has been no change. On referring to Mr. Taylor's letter on p. 66 it will be noticed that the history of these coils previous to 1875 is uncertain; all that is known is that they have the formal B.A. stamp, and it is stated in the Fourth Report of the Committee, 1866, that all the coils issued are correct to $\cdot 0001$ at the temperatures stated.

There is still another coil of some interest.* This is now marked  54. It was made in accordance with the suggestion of Chrystal in 1876, with a thermoelectric junction attached. Fleming compared it with his standards in 1879 and 1880. In 1884 it was again compared by us and found to have the value $\cdot 99658$ B.A.U. at $8\cdot 3$, with a temperature coefficient of $\cdot 000295$. It was then sent to Professor Kohlrausch at Würzburg for comparison with some mercury units constructed by Strecker, and was returned by him at the end of his experiments.

In 1888 it was again compared and found to be $\cdot 99653$ B.A.U. at $8\cdot 3$, with a coefficient of $\cdot 000290$. It will be seen that the change is $\cdot 00005$, which is within the temperature errors.

Thus we conclude, from this general account of the condition of the coils at present, that with the exception of the platinum iridium coils A and B there is no evidence of any change of as much as $\cdot 0001$ B.A.U. since the years 1874 or 1876, but that all the platinum silver coils and the two gold silver coils belonging to Mr. Taylor changed apparently by about $\cdot 0007$ B.A.U. between the time of their construction and the time at which they were examined by Chrystal and by Taylor respectively. This change may of course be a real one; we incline, however, to suppose that it is apparent only, and offer the following explanation, already several times referred to.

Hockin says in a note to his Table of Temperatures, 'British Association Report,' 1867, which gives the temperatures for the standard coils of the Association: 'The values given in the above table are deduced from the german-silver coil called B¹ used in your Committee's experiments in 1864.'

He does not seem to have compared among themselves the standards of various materials, but to have referred each to B. Now we are ignorant of the temperature at which the comparison was made, but we know he used the coefficient $\cdot 00032$. This at present is too high by $\cdot 00004$. If we suppose that Hockin made his determinations with the coils in ice, then this error in the temperature coefficient would lead him to a value for the coil at 15° , which would be too high by $\cdot 0006$.

Having once got a platinum silver coil supposed to be known, it would be natural to use it as a standard rather than any of the others, because of its low temperature coefficient, and the error made in the original determination of G would thus be perpetuated. This conclusion is borne out by the observations on Messrs. Elliott's coil No. 41, Table X. Its standard temperature fell apparently by 2° between the time of its issue by Matthiessen in 1864 and Hockin's comparison in 1879, and then rose

¹ This is not the same as our B.

again between 1879 and 1882. This would be accounted for if we suppose that Hockin's platinum silver standard was too low.

P.S.—November 1888.—Since the experiments detailed above were completed a considerable change has taken place in F. It is now almost exactly equal to Flat, that is, it has risen in value by $\cdot 00048$ B.A. Unit. Further investigations as to the cause of this must be left till the next report.

Second Report of the Committee, consisting of Professors TILDEN and W. CHANDLER ROBERTS-AUSTEN and Mr. T. TURNER (Secretary), appointed for the purpose of investigating the Influence of Silicon on the properties of Steel. (Drawn up by Mr. T. TURNER.)

In the previous Report of this Committee, presented at the Manchester meeting, an account was given of a series of experiments undertaken in order to determine the effect produced by silicon on the properties of the purest variety of iron met with commercially. For this purpose metal was taken from the basic Bessemer vessel at the end of the blow, before any carbon or manganese was introduced, and to this fluid metal weighed quantities of silicon pig, containing about 10 per cent. of silicon, were added. It was then shown that silicon rendered the metal quiet in the mould, and that in the proportions employed the metal was tough when cold, and welded well. The elastic limit and tensile strength were both increased by the presence of silicon, while the elongation and contraction of area were diminished; the appearance of the fracture also changed from silky to crystalline, and with over 0.13 per cent. of silicon in all cases the metal was so red-short that the ingots crumbled to pieces under the rolls.

The present Report has to do with a series of experiments very similar to those described last year, the chief difference being that ordinary basic ingot metal was used instead of the specially pure iron previously employed. In these experiments, therefore, the metal has been taken in the condition in which it would be sent into commerce, definite quantities of silicon have been added, and the product examined both chemically and mechanically. The method of procedure was as follows: In a covered fireclay crucible a weighed quantity of the silicious iron was melted, and into the red-hot crucible was run about 40 lbs. of molten metal, which was taken from the ladle about the middle of a cast. After allowing the contents of the crucible to stand for about a minute, the metal, which was still thoroughly fluid, was poured in to another red-hot clay crucible, in which the mixture was allowed to solidify. By this means a very thorough incorporation of the materials was obtained. The experiments were conducted, as before, at the works of the South Staffordshire Steel and Ingot Iron Co., Bilston. Mr. F. W. Harbord kindly superintended the works tests of the material; the mechanical tests were conducted by Professor A. B. W. Kennedy, and in each case duplicate experiments were made; the chemical analyses have been performed by Mr. J. P. Walton.

TABLE A.—Influence of Silicon on Ingot Iron. General Summary of Results.

No.	CHEMICAL ANALYSES. (By J. P. Walton)					WORKS TESTS. (By F. W. Harbord)				MECHANICAL TESTS. (By Professor A. B. W. Kennedy)						Differences so small as to be scarcely perceptible	Relative Hardness
	Si	C	S	P	Mn	Rolling	Hot	Cold	Welding	Limit of Elasticity	Breaking Load	Ratio of Limit to Break	Extension per Cent. on 10 inches	Reduction of Area per cent.	Work done per cubic inch

A general summary of the results is given in Table A., which contains both the chemical analysis, the works tests, and the mean of the mechanical tests of the specimens prepared as before described.

Specimen No. 1 was prepared from the metal taken from the ladle, it being poured into a red-hot crucible, and afterwards treated in exactly the same way as in the ten succeeding experiments. In this case, however, no silicious iron was added, and the values given are intended merely for comparison with those which follow. The analysis of this specimen was not made from any of the samples actually tested, but is what may be considered an average composition of such metal. The mechanical values are the mean of four experiments with metal from two separate charges.

The silicon pig used had the following composition:—Carbon, 1.96; silicon, 10.30; sulphur, 0.02; manganese, 1.90; phosphorus, 0.17.

On examining the results in detail, the following observations will be made:—

1. **CHEMICAL COMPOSITION.**—The silicon gradually increases from specimen No. 2, through the series to No. 11. The other constituents, though tolerably uniform, still show sufficient variation to influence the properties of the product, and allowance must be made for these differences in composition in drawing any conclusion as to the influence exerted by silicon.

2. **WORKS TESTS.**—It will be noticed that all the specimens examined rolled well, and that, with one slight exception, all behaved satisfactorily under the hot test. This is in very marked contrast to what was observed in the previous experiments, when silicod produced distinct red-shortness; the difference in the present case is doubtless due to the presence of manganese in the ingot metal. The cold or bending test was also satisfactory in all cases, with the single exception of No. 11, which contained 0.504 per cent. of silicon and 0.121 per cent. of phosphorus. In this sample it is not certain that the metal would have behaved in the same way if the phosphorus had been as low as in the other cases. In the welding tests the metal behaved well in every instance, showing that the presence of silicon has no perceptible influence on the welding property. In the cold and welding tests the results are the same as was noticed in the previous series of experiments.

MECHANICAL TESTS.—In the original metal both the limit of elasticity and the breaking load, which are given in tons per square inch, are rather higher than usual in this class of metal, while the extension and reduction of area are rather lower than is common. These differences are, however, not great, and may be accounted for by the comparatively small scale on which the experiments were performed.

•*Limit of Elasticity.*—This varies in the first six specimens (Nos. 2 to 7) over a maximum range of 1.65 tons, and these small variations are of such a kind as may be explained by differences of composition other than those of silicon. In the specimens with more silicon, however, there is a distinct increase in the elastic limit due to silicon.

Breaking Load.—This varies in a manner which closely resembles that observed with the limit of elasticity. In the first six specimens the variations are irregular, the maximum range being 4.1 tons, and this variation can be accounted for apart from any influence due to the silicon present. With more silicon, however, there is a distinct increase of the breaking load, and this is doubtless due to silicon.

Extension.—The specimens 2 to 7 have an extension which, though slightly lower than usual, still accords with what would be inferred from the elastic limit and breaking load. If silicon has exerted any influence in these specimens, it is not well marked, though the low extension may be partly due to this cause. With more silicon the extension is distinctly reduced.

Reduction of Area.—This follows much in the same order as the extension, and is distinctly lowered with the higher proportions of silicon.

These results may be summarised as follows:—

On adding silicon in proportions not exceeding 0·5 per cent. to ingot iron containing manganese, the metal rolls well, and does not show any signs of red-shortness; it welds perfectly with all proportions of silicon, and (with the somewhat doubtful exception containing 0·5 per cent.) is not brittle when cold. With less than about 0·15 per cent. of silicon the limit of elasticity, the breaking load, the extension, and reduction of area, are but little, if at all, appreciably affected by the presence of silicon, but with more than 0·15 per cent. of silicon the limit of elasticity and breaking load are increased, while the extension and reduction of area are distinctly decreased by the presence of silicon. The effect exerted by silicon in increasing the tenacity of ingot iron is not nearly so great as that of carbon. The relative hardness is very slightly affected by the proportions of silicon used in these experiments.

It is to be regretted that, largely on account of the outlay it would have involved, these experiments have been conducted on a comparatively small scale, the ingots used weighing only about 40 lbs. On this account it has not been found practicable to perform tests connected with resistance to shock, a point to which the attention of the Committee has been several times directed, and which is, from a practical point of view, of considerable interest.¹

Third Report of the Committee, consisting of General J. T. WALKER, Sir WILLIAM THOMSON, Sir J. H. LEFROY, General R. STRACHEY, Professors A. S. HERSCHEL, G. CHRYSTAL, C. NIVEN, J. H. POYNTING (Secretary), and A. SCHUSTER, and Mr. C. V. BOYS, appointed for the purpose of inviting designs for a good Differential Gravity Meter in supersession of the pendulum, whereby satisfactory results may be obtained at each station of observation in a few hours instead of the many days over which it is necessary to extend pendulum observations.

MR. BOYS has not yet been able to construct the instrument referred to in the last report. Meanwhile no new design has been received.

The Committee ask for reappointment and a renewal of the grant of 10*l.* made last year.

¹ A more complete account of the above experiments is in type, and will be published in the *Journal of the Chemical Society*.

Report of the Committee, consisting of Professor H. E. ARMSTRONG, Mr. J. T. DUNN, Professor W. R. DUNSTAN (Secretary), Dr. J. H. GLADSTONE, Mr. A. G. VERNON HARCOURT, Mr. FRANCIS JONES, Professor H. M'LEOD, Professor MELDOLA, Mr. PATTISON MUIR, Dr. W. J. RUSSELL, Mr. W. A. SHENSTONE, Professor SMITHELLS, and Mr. STALLARD, appointed for the purpose of inquiring into and reporting on the present methods of teaching Chemistry. (Drawn up by Professor DUNSTAN.)

THE Committee decided at first to restrict their inquiries to the teaching of chemistry in schools. With this object, in December last they addressed the following letter to the Head Masters of Schools and the Principals of Training Colleges, both in Great Britain and Ireland, in which chemistry forms a part of the curriculum. The list of these schools was compiled from the 'Educational Year-Book.'

COMMITTEE ON CHEMICAL TEACHING.

Dear Sir,—At the meeting of the British Association held at Manchester in September last, Professor H. E. Armstrong, F.R.S., Mr. J. T. Dunn, Professor W. R. Dunstan, Dr. J. H. Gladstone, F.R.S., Mr. A. G. Vernon Harcourt, F.R.S., Mr. Francis Jones, Professor M'Leod, F.R.S., Professor Meldola, F.R.S., Mr. Pattison Muir, Dr. W. J. Russell, F.R.S., Professor Smithells, Mr. W. A. Shenstone, and Mr. Stallard were appointed as a Committee for the purpose of inquiring into, and reporting on, the present methods of teaching chemistry.

It is felt that great difficulty exists at the present time in teaching chemistry to elementary students, owing chiefly to the absence of agreement among teachers as to the best modes of giving instruction and to the diverse views of examiners. It is hoped that an inquiry by this Committee will be valuable not only to teachers of elementary chemistry, but also to those who have the responsibility of examining in this subject. The members of the Committee venture, therefore, to hope that you will assist them by furnishing, at as early a date as possible, such a report on the chemical teaching in your school as you consider will be most likely to aid their inquiry, more particularly with regard to the following points:—

1. The objects with which chemistry should be taught in schools.
2. The difficulties that are met with in teaching, and the best way of obviating them; the influence exerted by external examiners on the character of the teaching.
3. The methods which, in your opinion, are most likely to render the teaching effective as a mental discipline, and as a preparation for subsequent instruction in the higher branches of the science or in applied chemistry.

The Committee will also be greatly obliged for information on any other points directly connected with the teaching of elementary chemistry; any data with which you may favour them will be regarded as con-

fidential, and nothing of a personal nature will be published without your previous consent.

In making any communication to the Committee, it will be convenient if you will kindly affix to the manuscript the paper which is enclosed.

I am, Sir,

Your obedient Servant,

WYNDHAM R. DUNSTAN,

Honorary Secretary to the Committee.

Five hundred copies of this letter were circulated, but only eighty-six more or less extended replies have been received; they include the majority of the largest public schools in Great Britain. These replies have been the subject of careful consideration by the Committee.

The schools which have reported represent a total number of 23,350 pupils, and of these 8,418 receive instruction in chemistry; that is, 36 per cent. It will be useful to summarise in this Report, by means of extracts from typical replies, the chief points of general interest which have been alluded to, particularly those that were raised by the three questions suggested by the Committee in their letter.

‘1. *The objects with which chemistry should be taught in schools.*’

There is almost unanimous agreement as to the high educational value of the science of chemistry. Teachers seem agreed that chemistry should be taught in schools with two objects: first, and mainly, on account of the mental training and intellectual discipline it affords; and secondly, for the sake of its applications in the different professions and trades which the boys may subsequently follow and also in its direct bearing on the facts of everyday life. This view of the importance of chemistry as a part of the school curriculum is well exemplified by the following extracts taken from the reports made by various schools, both large and small, and representing boys who afterwards follow a diversity of trades and professions.

I. ‘Chemistry should be taught in schools—(1) As an educational subject or mental discipline. In studying chemistry the pupils are led to cultivate habits of *observation*, because the statements made in chemistry are based on facts actually seen; of *reflection*, because the accurate statement of even the simplest observed fact requires not a little reflection; and of *reasoning*, because reasoning is required before one can decide that any one particular result in an experiment is due to some one particular antecedent circumstance out of several. Chemistry also is especially the science in which experiment can be most readily had recourse to by the pupil. (2) As a valuable branch of instruction. Supposing that the mental powers were not developed and strengthened by the study of chemistry, it might still be desirable that pupils should not leave our public schools wholly ignorant of the composition, properties, and uses of the materials of everyday life.’

II. ‘Science and history alone of the subjects taught in schools perform a twofold function. They give connection of ideas, logical power, and education in the fullest sense, while at the same time they store the mind with useful facts likely to make the possessor a more valuable member of the body politic. Hence chemistry may be taught to *all* boys just in the same way as ancient languages and higher mathematics, without any thought of the future career of the pupil, or whether chemical

knowledge is likely to be of practical use to him or not. In this way the practical demonstration of chemical facts becomes a great object-lesson, while chemical theory becomes an introduction to logic. Chemistry may be taught for other reasons:—(i) To enable boys who show no special aptitude for any other subject to obtain a scholarship and university education. (ii) As a special subject, likely to be useful for those who, having passed the preliminary arts' examination, intend to adopt a medical career.'

III. 'The objects with which chemistry should be taught in schools:—
1st. To make lads take a keener interest in natural phenomena. A few well-chosen experiments will excite their wonder, and at the same time create an interest in the secrets of nature. 2nd. To teach lads to see, *i.e.*, to develop their powers of observation. 3rd. To impress upon lads that there is a definite law of order in Nature. Lads soon see that from the same bodies under similar conditions certain fixed results must follow. 4th. To make boys logical and not too hasty in generalisation from a few isolated observations. Chemistry is peculiarly well fitted for this purpose. 5th. To direct the powers of destructiveness and constructiveness which are always so pronounced in boys, since they soon learn to be interested in simplifying many complex forms and in building up others. 6th. To impress upon lads, as soon as possible, that everyday life must necessarily be influenced beneficially by a knowledge of the chemical properties of a very few simple bodies and the laws which determine their mutual interaction.'

IV. 'There are, I think, two considerations to be kept in view:—(a) the general educational value of the work which gives chemistry a claim to be considered a necessary part of any liberal education, whatever be the profession in view; (β) the necessity of teaching chemistry on such lines that the instruction given may be a sound and valuable apprenticeship for such boys as may be led to devote themselves specially to this subject in the future.'

* The following sentences (V.) were written by the head-master of one of the first public schools in England.

V. 'I think that the objects with which chemistry should be taught in schools are three:—(a) To make every boy acquainted with common scientific facts, useful to him in every branch of life. (β) To give opportunity to boys with special aptitude for science to take up and develop the study; many a boy who seems dull at languages brightens over science. (γ) To enlarge the mind by the suggestion of new methods and processes and by the illustration of the mode in which Nature works.'

VI. 'I have found that the teaching of chemistry, besides its direct value for professional and business purposes, is of great importance as a means of developing the minds of boys who have no aptitude for other subjects. I have found that many boys who cannot get on at classics and mathematics take an interest in and learn chemistry, thus being greatly encouraged in their other work by the knowledge that there is something that they can do.'

VII. 'Chemistry should be taught chiefly for mental discipline. Practical chemistry is almost the only school subject in which hands and brains are equally employed.'

VIII. 'In schools chemistry, like other subjects, is, no doubt, taught with a double view—mental training and the imparting of valuable know-

ledge. As to the former of these, the subject is not, in the opinion of the present writer, of great value, for the methods of demonstration as they can be exhibited in a school laboratory are not very rigorous and logical, and at the best seem rather to afford a strong presumption than a satisfactory assurance in favour of any particular conclusion. As to the latter object, it may be said that it is not one about which educationists generally are very enthusiastic. At the same time, if there is any subject more than another the knowledge of which is desirable it is chemistry. The entire change of mental attitude towards physical surroundings, which even a slight knowledge of the principles of chemistry induces, is most noticeable, and boys find it both a source of healthy wonder and, though they do not observe it themselves, a great mental stimulus. There is, of course, one other object with which chemistry may be taught, namely, for the sake of those who will find it directly useful in after-life. But as they are, after all, only a small percentage of the whole, the argument of practical utility is one which cannot be advanced as in itself a justification for teaching the subject.'

IX. 'Chemistry should be taught in schools while boys are comparatively young, in order that those who have no taste for classics may find some work in which they can take a practical interest. There are boys who, without being stupid, have no taste whatever for books, and the chance of practical work, like chemistry, for which they can see some use of an obvious kind, may prevent many a boy from becoming a confirmed idler. The study of chemistry, therefore, should be encouraged as a distinct benefit to the character of many boys. It should also be encouraged for the public good, because any boy so interested in early life may be led to devote his after-years to the pursuit of scientific subjects. And again, it should be taught in schools to enable boys who go into business now very young to have some slight knowledge of scientific facts of an elementary kind while they still have time to learn.'

X. 'All my experience shows that even to young children chemistry may be made the threshold of the fairyland of science, and that by means of it they may early acquire a profound sense of the rigorous, unyielding nature of law and of the unity in the midst of diversity which pervades the world around us. Again, as a mere discipline for the intellect, I believe chemistry is destined to take the place of Latin and Greek grammar, when a definite course of teaching has been laid down, and teachers have themselves mastered that course as thoroughly as former teachers had mastered their accidence and syntax. To make the pupil aware of the existence of an unknown, unexplained, inscrutable side to every, and even the simplest phenomenon, is to awaken desire, expectation, pleasure—all the antecedents of healthy mental effort, and the difference between the daily, hourly life of one who has thus become conscious of the literally infinite, ineffable nature of things around him, and that of one who thinks he knows all about them, is immense.'

XI. 'Too much weight may easily be attached to the objection often urged against chemical teaching (and, indeed, against the study of other branches of natural science), that it fails to cultivate good taste and good style; that the learner is brought into contact merely with material facts and not with human thoughts, and so acquires a character and mode of expressing himself as hard, rough, and unsympathising as the laws of Nature with which he deals. It is certainly impossible to avoid noticing that the abstracts of lectures and answers to examination papers shown

up by those who have been, or are being, well trained in "the humanities" are composed in much better style than the productions of boys who have had less advantages of the kind, or who, from their dulness in other subjects, are considered to be exactly fitted for learning natural science. But the power of refuting this objection rests with the teacher. If he refuses to pass over bad spelling and bad grammar, if he takes the trouble not merely to point out slovenliness of expression, but to show how it may be corrected, and if the learner is compelled to rewrite any careless, inaccurate work in better form, there seems no reason why an account of the two oxides of carbon, including an intelligent comparison of their properties, may not be made as good an exercise in English composition as an essay on points of Greek and Roman history.'

2. *'The difficulties that are met with in teaching, and the best way of obviating them; the influence exerted by external examiners on the character of the teaching.'*

Much might be written about the various difficulties which are alluded to in these reports in answer to the second question suggested by the letter of the Committee. The chief difficulties are stated to be those which arise from:—(i) Defective organisation and considerations of expense; (ii) the lower value attached to chemistry, as compared with other subjects of the school curriculum; (iii) the time which is devoted to the subject; (iv) preparation for various examinations; (v) absence of good text-books; (vi) dearth of properly qualified teachers.

(i) The expenses incidental to chemical teaching and the defective organisation, which is often the result of insufficient endowment, are the subjects of general complaint. Sometimes no laboratory is provided; frequently the laboratory accommodation is inadequate; and it appears that the details of the preparations for lectures and practical work generally devolve on the teacher himself. The following statements may be quoted. The first two are from the reports of small schools.

XII. 'We have no laboratory or other facilities for practical work, and so our experiments have to be very simple and our work very elementary.'

XIII. 'The chemical teaching is quite elementary, and there is no apparatus, so that it is only taken as a lesson with figures drawn and explained on the black-board.'

XIV. 'Thus our difficulties are:—(a) Having too many to teach. I am responsible for about 160 boys, and have no help. (b) The want of a large laboratory. We have a small but very good laboratory. There is, however, only accommodation for 12 boys, while I always have about 70 doing practical chemistry in an aggregate of 6 hours a week. Hence each boy gets only one hour a week. (c) The want of sufficient time to prepare for experimental work. The whole of my school time, except three hours, is taken up in teaching, so that all preparation has to be done either before or afterwards, the practical result being that I am obliged to limit my experimental teaching to the two lowest and the highest forms.'

XV. 'The chief obstacle to the effective teaching of chemistry here is the poorness of the laboratory—a room in the basement, low pitched, ill lighted, and worse ventilated, accommodating only 15 boys, and in such connection with the other class-rooms as to make some of them

almost unbearable when experiments are made with any foul-smelling gas.' [This school contains 500 boys.]

XVI. 'To lecture properly, a master must have an assistant for the experiments. I do not know what is the rule; I hope I am an exception, for I am without one. I make use of one of the promising boys to help in the preparation preceding a lecture. This is not sufficient. A master cannot easily conduct his experiments, keep order, and carry on a judicious questioning and explanation at the same time.'

XVII. 'Every teacher of chemistry who has several lectures to deliver in the course of the week ought to have the services of a fairly intelligent assistant, who can get ready most of the experiments for him, or he ought to have extra time allowed him to do this himself. Of course it is possible to utilise the services of the more advanced pupils for the purpose, but this does not effect so much saving of time as might be thought, owing to the want of experience on the part of the boys, who in many cases require so much supervision that it is shorter for the teacher to do the work himself.'

XVIII. 'We have just abandoned the subject owing to its ruinous expense if taught thoroughly.'

XIX. 'We have no laboratory and have to do the best we can with a table in a class-room. Experiments are shown, but not performed by the boys for this reason.'

XX. 'Schools are often badly equipped with a suitable lecture-room, laboratory, and apparatus, partly from poverty and partly sometimes from inability on the part of the head-master or governing body to appreciate the needs of the subject.'

XXI. 'Another difficulty is that in many cases the teacher has not time to prepare adequate experimental illustration. Until recently the chemical teaching in this school was done by the second master, who had the whole of the school hours not engaged in teaching science occupied in his own form in general subjects. A public day-school does not usually (like a science college) possess paid demonstrators and assistants, hence, unless the teacher has a considerable amount of time not actually occupied in teaching, it is impossible for him to make and set up apparatus for experiments in a proper manner, and experiments that constantly fail are worse than none.'

(ii) The following statements deal with the difficulties that ensue from the relatively low place which is generally afforded to chemistry in the school curriculum, and the low value which is assigned to it in public examinations as compared with the value attached to other subjects. This, it is said, often leads to the restriction of chemical teaching to inferior boys, some of whom may have failed in classics and other subjects. The best boys may leave the school having received little or no instruction in chemistry.

XXII. 'One difficulty arises from the low standard of public opinion as regards science. This is chiefly due to the extraordinary and utterly unaccountable view (confined, I think, to England and America) which classical men have always had of scientific studies. In this school, owing to the exceptional liberal-mindedness of the powers that be, this evil is unknown, but in other schools where I have taught the jealousy between those who represented different kinds of study was enormous, and clever boys were therefore more attracted to literature than to science.'

XXIII. 'As regards the difficulties in teaching chemistry, I think per-

haps the first is non-classification. The boys are sent to chemistry lectures grouped according to classics; the result is confusion. Take the fifth form, for example. It is sent into the laboratory for an hour's lecture. In that form you have some of your promising boys, also some of the weak ones, very good classics possibly, whom to teach chemistry is, you know, 'hopeless. But the work must be done, so you take a medium course, pitching your discourse to suit the average boy; you must be very careful to aim low or you will certainly hit nothing. In doing this your lecture is below the promising boys, who feel a growing contempt for you or your subject, and at the same time the lowest boys are wearied by matter which they cannot grasp.'

XXIV. 'Two difficulties are:—(i) Want of sympathy with natural knowledge on the part of the majority of university men who take to school work; (ii) strong adverse traditions in many schools backed up by the fashionable superstition that literary rather than scientific studies constitute the education of a gentleman.'

XXV. 'The difficulty is that parents do not yet recognise chemistry as a "paying" subject, consequently their boys neglect it.'

XXVI. 'A serious difficulty is caused by the fact that boys may join a class in any term. This may not be a great evil in the case of languages or mathematics, but where from the very nature of the subject it is necessary, in order to understand and benefit by a lesson, that the preceding lesson should be first mastered, the case is altogether different, and it is not clear how this and the kindred difficulty of grouping in one set boys of very unequal powers and attainments can be obviated, seeing that schools are classified on other lines, generally according to proficiency in classics.'

XXVII. 'I believe that one of the great stumbling-blocks in the way of chemical teaching in day-schools is, that boys are often sent to the science master in classes determined by their position in classics or English subjects, so that there is no proper gradation in the teaching. This obtained here until recently, but now, by simultaneous teaching by three masters on two afternoons a week, it is possible to group the boys in the senior school according to their proficiency in science (mainly chemistry) alone. The result has been a considerable improvement in the quality of the work.'

XXVIII. 'The scholastic disrepute in which chemistry is held is apt to lead a head-master to devote to it the least mentally qualified boys, who have absolutely failed on the classical side.'

(iii) It appears that the time which is usually allotted to chemistry in schools is altogether inadequate, and frequently this defect seems to constitute one of the teacher's greatest difficulties.

XXIX. 'I suppose few grammar schools give more time to chemistry than four hours a week, and so long as competitive examinations assess chemistry at one-quarter the value of mathematics, and one-eighth that of classics, more time cannot be expected. When it comes to be recognised that the mind which is scientifically trained is most likely to produce work valuable to the community, and at the same time is best suited to grapple with the practical problems of everyday life, all this will be changed.'

XXX. 'This school contains 500 boys. The average number of those who receive instruction in chemistry is 30 and the time allotted to the subject is three hours a week.'

XXXI. 'The difficulty is to make all pupils take a real interest in the work. In the short time which is allowed to the subject it is apt to become a mere collection of facts in the boy's mind. It is a curious fact that a double labour is expected from the teacher of science, namely, a general development and quickening of the reasoning faculties, and the teaching of examination-chemistry at the same time; and all this has to be done in two hours a week! Parents at any rate tacitly pay a very high compliment to the resources of science when they expect this. As a matter of fact, the unfortunate science master very naturally leaves the great work of development to the master who monopolises the remaining 26 hours of the week's work.'

XXXII. 'The time allowed to the 65 boys who learn the subject is one period a week of 45 minutes.'

XXXIII. 'All the pupils who are taught chemistry—491—devote two hours per week to the subject, and 110 of these have in addition a weekly lesson in laboratory practice, lasting one hour and a half.'

(iv) A consideration of these replies has fully established the important fact that the chemical instruction which is given in schools is very largely influenced and guided by the requirements of the various Examining Boards, such as those of Oxford and Cambridge and of the Science and Art Department. Abundant testimony has been received on this point, and it is frequently declared to be a great, though apparently an inevitable, evil. The quotations cited below are selected as representing schools of very different grades.

XXXIV. 'The influence exerted by external examiners on the character of the teaching. This has always been to me the most subversive of good teaching and most damaging to the character of the work. I have had a large experience in the working of the various public examinations, and I unhesitatingly say that they cripple the work of teachers, afford no safe index as to the quality of the work, and lead to a system of book-work cram which militates against anything like mental discipline and against subsequent instruction in the higher branches of the subject.'

XXXV. 'But all difficulties are nothing compared with those that arise from the personal peculiarities of examiners. Unless with special pupils who, having spent most of their time on chemistry, have been able to acquire some knowledge of all its branches, a teacher is never sure that he will be able to prove to an examiner that he has taught any chemistry at all.'

XXXVI. 'It will be seen that the examinations for which our pupils are prepared are those of the Cambridge Local, the College of Preceptors, and the Science and Art Department, and the preparation for each is so varied that it has a very bad influence.'

XXXVII. 'The influence of external examiners, in my opinion, is too often to encourage mere cramming to meet out-of-the-way questions.'

XXXVIII. 'A class was formed from the pick of the school in connection with the Science and Art Department. My salary to a certain extent depended on the results of the May examinations. Since the number in the class had to be limited, I naturally chose only those boys who I thought would have the best chances of getting through. For a great part of the year chemistry would be treated as a by-subject, it was only for a month or so that it had its due share in the curriculum of the school, and I must conscientiously admit that during the short period before the examination I simply crammed the minds of my pupils with

equations, properties, graphic formulæ to such a degree as to ensure passing, which they all did. I was not surprised to find that in a short time all had been forgotten. This system is adopted at many places.'

XXXIX. 'The teaching of chemistry here is entirely regulated by the Science and Art Department, for the simple reason that it would not exist as a class subject without the pecuniary aid rendered by the Department. I believe some really good work is being done; but the teacher is very much of a machine, and, however conscientious he may be, he must primarily, under the circumstances, teach for examination, and at times neglect what would be useful to his pupils because it would not be useful for examination.'

XL. 'In this school chemistry is optional, and the primary object of its existence is the advantage of those boys who are going in for examinations in which it will prove useful.'

XLI. 'There is great variation in the standards and methods of various examinations. Three things are specially to be complained of:—(a) the bookish nature of some examination papers; (b) estimation of the value of answers by comparison with text-books by inferior men, not always the authors of the papers or themselves real chemists; (c) want of judgment in setting papers arising often from ignorance at first hand of the conditions of school work.'

XLII. 'With respect to examinations, I do object to men examining boys under sixteen who have never taught them, and who, therefore, do not understand that the work of such students must differ not only in quantity but also in quality from that of older pupils.'

XLIII. 'I believe that 90 per cent. of those who are now taught chemistry in this country are taught with the view of passing one or other of the examinations held on the subject. Further, I believe that most of the difficulties of teaching chemistry are difficulties of teaching it so as to comply with the requirements of examinations. Some one has said that in the regulations of the Science and Art Department so much is required to be known that there is no time for anything to be done, which is an exaggeration of what I mean. With ordinary teachers one thing is necessary—their pupils must pass. When that is secured they may indulge in such novelties of method and procedure as they like, but not until then. It would avail me nothing to say that my instructions were faulty, that I knew and followed a more excellent way.'

XLIV. 'As to the influence of examiners. In my own teaching it has been for the last few years *nil*. I have given up trying to fit the chemical instruction to the doubtful requirements of examination; to do so would take the vitality out of one's teaching and contract it.'

XLV. 'With regard to the influence of external examiners on the teaching, there is no doubt that this is very great, and that the character of the teaching in our schools must depend in these high-pressure examination-days on the requirements of the examiners.'

XLVI. 'We have subjected our boys to two examining bodies—the Science and Art Department and the University Board. In successive years the boys from the same teaching universally succeeded under the former and almost universally failed under the latter.'

XLVII. 'The examinations have been chiefly those held in connection with the Science and Art Department, South Kensington. These examinations have been for some years back highly satisfactory, and no undue prominence has been given to any one branch of chemical science.

They certainly do exert an influence on the character of the teaching, but it is a restraining and beneficial influence.'

XLVIII. 'The influence exerted by external examiners on the teaching is decidedly beneficial *when the examiners are experienced men.*'

XLIX. 'The influence exerted by external examiners on the character of the teaching is practically *nil*. They send their questions and substances, examine the results, and write their reports, and, with rare exceptions, never make a suggestion as to how the teaching may be improved or better results obtained.'

(v) The absence of good text-books suitable for use in schools is frequently stated to be a source of difficulty.

L. 'One of the chief difficulties in class teaching is the want of a suitable text-book, more especially when preparation is an important factor. A text-book should without any great amplification on the part of the teacher make itself intelligible to the boy on reading it for the first time, and it should not be overladen with facts.'

LI. 'We want a good school text-book. Existing books entirely lack connection in their various parts, and are generally made up of a series of more or less isolated facts grouped loosely under various heads. They are also too diffuse and wordy, and, therefore, very unsuited to a boy with but a limited time to prepare his lessons.'

LII. 'An additional difficulty is found in the absence of a satisfactory text-book, notwithstanding the multitude already extant, and this difficulty is not diminished by the consideration that, as a rule, the science master is required to devote a great portion of his time to teaching other subjects. According to my idea, the kind of book required is one that recognises the close connection between the lecture work and the practical work of the pupil; in fact, a book something after the plan of Huxley and Martin's "Biology."'

LIII. 'The greatest difficulty we meet in teaching chemistry is the want of a suitable text-book on which all our lecturers can base their teaching. Boys sometimes get different definitions of the same term, and a master does not know exactly how much boys have learnt in another class.'

LIV. 'Text-books are another difficulty. I have never found one yet that I liked to put into the hands of boys, for I have generally found that they are too elaborate and complete, using, sometimes, language which the ordinary schoolboy does not understand, and describing here and there experiments which he certainly cannot grasp. I have not found a book which I could put between the "Chemistry Primer" (which with the "Physics Primer" is always my preliminary course) and such a volume as Thorpe's or Roscoe's; these contain a great deal of matter too difficult and minutely exact for class work.'

LV. 'Further, there is the eternal text-book difficulty. A book at once clear, brief, and accurate is a desideratum.'

(vi) Some head-masters complain that they are unable to obtain properly qualified teachers of chemistry.

LVI. 'Difficulties arise from the circumstance that there stands before the class a chemist who is not a teacher, or a teacher who is not a chemist.'

LVII. 'The scholastic disrepute in which the subject is held is apt to affect the teacher. It is much easier to obtain a well-qualified teacher of classics than an equally well-qualified one of natural science.'

LVIII. 'Our two great difficulties here are:—(1) To get men, for

anything we can offer, who are at once chemists and teachers. Mere chemists are of no use from a pedagogic point of view, and even they would be hard to get. I am convinced that a *teacher* who had a strong grasp of the principles of the science could, and would, make it an eminently valuable means of mental training. (2) The entire non-recognition of chemistry by the two universities in the earlier stages of their arts courses.'

3. *'The methods which, in your opinion, are most likely to render the teaching effective as a mental discipline, and as a preparation for subsequent instruction in the higher branches of the science or in applied chemistry.'*

A great deal has been written in reply to the question as to the methods which ought to be followed in teaching elementary chemistry.

It is clear that the older plans of teaching, which are still largely used, are felt to be partly unsatisfactory, and that by modifying them chemistry might be made much more valuable as a mental discipline for boys. In particular protest is made against the undue proportion of time which is frequently assigned to qualitative analysis; indeed, the majority of teachers do not consider this to be the most valuable part of the subject. Others hold that it presents many advantages, and is, on the whole, the best adapted to school work, especially when instruction has to be given to large classes of boys. But while most teachers strongly deprecate a rigid adherence to the present system, and a few are able to point out the general lines on which the teaching might be more usefully conducted, it is evident that very few, if any, have yet put into operation a remodelled system of instruction. In fact, it appears that teachers stand very much in need of advice and assistance in preparing a modified scheme of teaching suitable for general adoption in schools. It has several times been suggested that this Committee might be able to render important help in this direction.

The following quotations are typical of many of the replies which have been made. They are written by the head-masters or science masters of both large and small schools, and are here reproduced, not only because they allude to some of the principal defects of the present methods, but also on account of suggestions they contain which seem likely to be valuable to those who are anxious to make chemical teaching more effective than it is at present.

LIX. 'The teaching should be experimental in all cases. The experiments need not be numerous, but apposite, and the utmost got out of them both directly and indirectly. I find, for example, that I can get a good hour's work out of boys in the lower forms with such subjects as the separation of sand from a solution of salt, the action of water on lime, or the action of nitric acid on copper. I find that the same plan of limiting the attention to one or two important points is also most effective in the upper forms when the exigencies of examination-work admit of this kind of treatment. Notes of lessons should be relied on rather than text-books. I find, for example, that the ground covered at previous lessons is always known, but that I get next to nothing out of a set lesson from a book. This will be sure to follow from an experimental method of treatment. Above all, I would suggest the entire remodelling of all school examinations and the placing them in the hands of men who have had experience in teaching,

and know, therefore, what to expect of boys, rather than in those of men fresh from the "schools," and with only the experience of university teaching. I should also like to see the range limited and the examination papers graded. The extent of the ground covered by the Local Examination papers of the universities is too great for such schools as this, though Oxford has recently much curtailed them.

'I am led to hope that your Committee may see its way to step in and produce something like uniformity and system. Would it not be possible to draw out a scheme of teaching divided into "grades," and suited to a progressive course, as also to issue yearly sets of examination papers adapted to these different grades? I sincerely trust that this may be one of the results of your inquiry, for I feel sure that examination by so high an authority will have a most beneficial effect on science teaching, and have a value in the hands of examiners impossible under any of the present systems.'

LX. 'It is, in my opinion, no use crying out against the system of examinations in this country. For years to come the nation will go on demanding results and getting them. Can those results be made more worth having? I believe they can. It lies entirely within the power of the eminent and working chemists of the country to effect great and useful reforms almost at once. It should be acknowledged that the present requirements are obsolete. Looking at the enormous and ever-increasing number of important and interesting facts, has not the time come when chemistry should be taught to beginners as biology is taught? Instead of reading about hundreds of plants and animals, a student becomes practically acquainted with about a dozen of each at first hand. Why should not a similar plan be followed in chemistry? Why should not a thorough study of chlorine include all that an elementary pupil needs to know about the halogens? The principal member of each group of the non-metallic elements might be selected for special study. As to the metals, half-a-dozen, which might be varied from year to year, if really mastered, would be much better than the knowledge which is required of them under the present system. Room would thus be found for a few organic compounds. It is pure pedantry to maintain any longer the arbitrary distinction of inorganic and organic chemistry in a first and general course. As to analysis, I think the present comparatively complete course should give place to a sound knowledge of the separation of some half-dozen substances, and the time thus saved could be devoted to easy exercises in quantitative analysis. There can be no doubt that quantitative analysis is within the reach of any student who can perform a good qualitative analysis. What I have proposed amounts to rewriting a syllabus for a first or general course of chemistry, on the basis of selecting a few typical substances and making a more or less complete study of them, and, with regard to analysis, to restrict the substances to be studied, but to require the elements of gravimetric and volumetric determinations.'

LXI. 'To render the teaching of chemistry of educational value it must be made inductive, and not chiefly and largely deductive. The guiding motto should be, "Prove all things." Experiments should be made with as simple apparatus as will secure the desired result. In the earlier lessons avoid all definitions, all hypotheses of atoms and molecules, of atomic weight and of "bonds," but early establish the constancy of composition of compounds and the equivalent weights of certain elements in

combining with or displacing one another. I should like to see some encouragement given to the historical aspects of chemistry. I have found that explanations of when and how the chief elements, acids and alkalies came to be known add much to an intelligent interest in the subject.'

LXII. 'It has always appeared desirable that a boy should approach chemistry in the same way that all the founders and builders-up of the science have done: viz., not by first reading a printed account of facts and then verifying them or seeing them verified, but by studying the different forms of matter as substances hitherto unknown, the properties of which have to be investigated for the first time and compared with those of other substances. With this view the experiments shown are considered as questions put to Nature, the answers to which are as little known to the lecturer as to the learners. No predictions are made as to the results, although boys are not unfrequently asked what, arguing from experiments previously shown or the properties of analogous substances previously examined, may be expected to occur. All apparatus used is described; the reasons for any special arrangement of it being explained fully. Elaborate forms of apparatus with a profusion of drying tubes, Woulf's bottles, fantastically bent leading-tubes, are avoided as far as possible, their tendency being to draw off attention from the main point of the experiment. The arithmetical side of chemistry is not very much enlarged upon; it seems hardly desirable that boys should look upon experiments as pegs on which numerical problems are to be hung. Too much time may easily be spent in elaborate calculations on the quantity of zinc required to obtain enough hydrogen to decompose the nitrogen monoxide produced from ten grammes of ammonium nitrate. Innumerable examples, however, illustrative of important laws, such as those of Gay-Lussac and Avogadro, and of calculations actually required in quantitative work, are frequently set, generally at the beginning of each lecture, in reference to some point explained in the preceding one. No symbols, formulæ, or equations are used at first—not, in fact, until the properties of three or four elements, and of some of their compounds, have been studied and the laws of chemical combination deduced from them. Then, and not till then, it is thought that a learner can appreciate the value of Dalton's atomic theory in accounting for the facts he has observed, and can see the advantage of a system of chemical shorthand, and use it with intelligence and discrimination.'

LXIII. 'The method, in my opinion, most likely to render the teaching effective as a mental discipline is mercilessly to sweep off a large proportion of the facts at present dealt with, to confine the attention of the pupil to those that for various reasons are the most important, and to use them always as illustrations of general laws. For this purpose, there must be agreement among teachers and examiners. I do not think it beyond the scope of your inquiry to suggest that, to make chemistry or any natural science do all that it can do towards mental discipline, there must be an attempt to use it as a means of destroying the contempt which familiarity breeds in us all towards common things. Unless you can call forth the interest of your pupil, his admiration, even his reverential awe towards the mystery of Nature, you have perhaps done more harm than good.'

LXIV. 'Eternal analyses of simple salts and mixtures such as are required by examinations of the present day weary and worry the student,

waste his valuable time, and throw away labour which in nearly every individual case would be most profitably spent in carefully studying and testing some important laws or principles of chemistry, and which would make the student's knowledge of the subject thorough and personal. Chemistry is essentially an experimental science. The great value of the study of the whole subject lies in the practical work done and in the method of building the theoretical structure on the practical knowledge. It is therefore absolutely necessary to have a thoroughly good laboratory with a lecture-room attached, so that collective and individual work may be carried on with equal facility. At the present time, in our schools and colleges there is too much working for examinations, and the requirements to pass such examinations are as narrow as paper legislation can make them. The student is for ever testing mixtures or performing some exceedingly simple gravimetric analyses. He is tied down, has his knowledge fettered instead of having it expanded, and never reaches the more advanced and useful principles of chemical science, which he can only dream of from the hearsay of his text-book.'

LXV. 'There is no scale of value of the different parts of chemistry; there is no recognised system as to which should be taught first. I have known boys obtain scholarships simply because their teacher had been recently a pupil of their examiner and knew the kind of questions he was likely to set. The ordinary text-books, lectures, and practical work do but little for even the hardest worker. We want an authorised code of work issued by a consensus of the highest authorities.'

LXVI. 'I object strongly to boys in a laboratory being allowed to mix different solutions in test-tubes, day after day, to find out whether precipitates are formed or not. I have a high opinion of the advantages derivable from the teaching of chemistry when none of the harder parts are shirked, as a valuable mental discipline, and as giving, with drawing, the best means of teaching an ordinary boy the use of his hands as well as his head.'

LXVII. 'The result of the absence of practice in quantitative experiments is to create an unnatural breach in the minds of pupils between the actual phenomena of chemical action and the theories by which such phenomena are to be explained. It might be found possible to treat the subject more logically if some attempt were made to teach the facts in a more natural order. The historical sequence by which the science has attained its present proportions might form the basis of a rational arrangement of the parts of the subject. In this way, by placing the pupils in the attitude of mind of original discoverers, the logical necessity of theories to account for the facts would give them more real meaning and interest. I am not acquainted with a text-book suitable for school use in which such an order is followed.'

LXVIII. 'Boys have been lectured to as if they were students, thereby producing a condition of things described by some writer as the perfect paradise of a boys' school, where the masters learnt the lessons and the boys heard them. Chemistry should be taught as everything else is taught—by making the boys do the work themselves—and the lesson should be a system of question and answer.'

LXIX. 'The calculation of chemical quantities, involving atomic weights, ought to come quite late in the course, so that the atomic theory is kept in the background at first. The pupil should make several experiments on the diffusion of gases and liquids which will lead up to the idea

of molecules. I must say that I think that "equivalents" should be used for some time before any reference is made to atomic weights. As to cramming a boy in the methods of writing equations, and finding how much sulphuric acid and zinc will make so much hydrogen, I can only say that, as the boy never attempts to carry it out in practice, and that if he did he would find his calculations all wrong as compared with his results, he had better leave them until late in his course, for their symbolic value and, in many cases, real worthlessness can only be estimated by a worker in quantitative analysis. I think a boy's practical work should undergo great alteration. At present he is examined in "simple salts," so of course he is prepared for that by a system of "test-tubing" which teaches him very little. He ought to start as far as possible with elements which he knows, such as sulphur and iron, and he should prepare certain compounds which contain them. He should then study the action of metals on acids, and the salts formed; cases of oxidation and reduction; preparation and properties of gaseous elements and compounds.'

LXX. 'In order that chemistry may be a useful subject for the education of boys, it seems to me necessary that it should be taught from experiments involving measurements. Other experiments may be amusing, but do not appear to afford food for severe or productive thought. It seems to be now generally admitted that boys should be led as far as possible to make inferences from chemical experiments for themselves. If they are to be taught the principal facts of chemistry in this way, it follows that the experiments must be of the former nature. It seems to be an evil that so much importance is attached in many examinations to qualitative analysis, which appears, from an educational point of view, to be one of the least valuable parts of the subject. The result is that teachers are compelled to spend the time given to laboratory work on this, to the detriment of experiments of a more instructive kind.'

LXXI. 'For beginners the illustrated lecture, well supplemented by periodical questioning, examination of note-books, &c., seems the only feasible way of teaching large classes of, say, thirty or forty. When the class is very small the lecture can be largely replaced by laboratory work, in which the experiments are performed by each individual student. This seems to me the best method; but my experience is that it is impossible to satisfactorily conduct *large classes* of *young* boys in the laboratory except in such simple experiments as the action of metals on acids, which can be done with a few test-tubes and other very simple and inexpensive apparatus, the breakages being too serious in an ordinary school if it is attempted to go through the preparation of all the commoner gases with a large class of beginners, in laboratories as they are usually arranged. I think more satisfactory results might be obtained with such classes if a part of the laboratory were specially arranged for the purpose, a bench (with only a few necessary reagents) in the form of a semicircle being used, the students *facing* the teacher, who would stand inside the semicircle. In such a class the students would all perform the same experiment after being shown it by the teacher. With rather more advanced students I think the separate system is better, all students not working at the same experiment, as this obviates the necessity of providing a large number of pieces of apparatus of the same kind, and allows a quicker student to make more rapid progress. I think it is very important that quantitative experiments should be made as early as possible; but here again my experience is that young

beginners cannot be trusted with balances sufficiently delicate to be of much value. The stereotyped "test-tubing" course examination of simple salts and mixtures is certainly a very inadequate laboratory course taken by itself; but it has, I believe, its advantages for school purposes in teaching care, order, and cleanliness, and it serves well for the middle classes of the school if properly supplemented by class-teaching, in which the chemical actions concerned in the testing are carefully considered.'

LXXII. 'Chemistry cannot properly be taught apart from physics; there is a physical side to every chemical phenomenon. Lecture work should precede laboratory work, and continue *pari passu* with it. Analysis rationally (not mechanically) taught is an excellent mental training. The two should be closely correlated; exercises should be given in the laboratory preparatory to or suggested by the subjects treated in the lectures, and facts learnt in the laboratory should be turned to account in the lectures. The teacher must not be trammelled by text-books: these must be his instruments, not his masters. Quantitative treatment of subjects in the lectures should be introduced as far as possible from the first, and as pupils advance they should be trained individually in the use of the balance. Numerical exercises based on (not as a substitute for) lecture demonstration help to give fixity and precision to ideas. Pupils should be trained to think out in their note-books the connection between experimental demonstration and theory, and not have notes dictated to them to be committed to memory. Their knowledge should be tested by frequent short examination papers.'

LXXIII. 'With regard to the practical work in the laboratory, the value of which cannot be over-estimated as a means of bringing a boy into real touch with his bookwork and developing in him those valuable qualities of patience, accurate observation, and powers of deduction, so especially necessary to the student of science, analyses of complicated mixtures not found anywhere in the universe are no longer now considered as the object to be aimed at. But there is still too much tendency to regard mere analysis as the aim and object of laboratory work. Rather should a boy be introduced to a progressive course of work which illustrates the more important principles of chemistry, and so be enabled to test the truth of these for himself. Here especially a good text-book of practical work is required, as a busy teacher finds it so difficult to get time to devise as well as supervise. Such a course of work must necessarily be limited in many schools, owing to the want of sufficient apparatus or the short hours of work. But still something may be done in this direction, and the mental training will not only be of infinitely more value to the special student, but also to the ordinary boy, who will not be much the wiser for having gone through a course of simple and complex analysis only. I think your Committee might do much towards smoothing the path of teachers by drawing up a memorandum addressed to the head-masters of schools suggesting points for their consideration, and asking them to meet the Committee's views on the subject as far as lies in their power.'

The Committee feel that these reports have put them in possession of the actual facts connected with the teaching of chemistry in schools, and have made it clear that something should be done in the direction of promoting a more uniform and satisfactory treatment of the subject.

The Committee think that some suggestions might now be made as to the method of teaching chemistry which should be followed in schools. If this can be done, it will certainly confer a great benefit on both teachers and examiners, and will be likely to lead to a more emphatic recognition of the merits of the science as an instrument of elementary education. The Committee accordingly ask for reappointment.

Report of the Committee, consisting of Dr. RUSSELL, Captain ABNEY, Professor HARTLEY, and Dr. A. RICHARDSON (Secretary), appointed for the investigation of the action of Light on the Hydracids of Halogens in presence of Oxygen. (Drawn up by Dr. A. RICHARDSON.)

DURING the past year this Committee has made numerous experiments on the decomposition of gaseous hydrochloric acid, under the combined influence of sunlight and oxygen.

A series of bulbs containing a mixture of moist hydrochloric acid and varying quantities of moist oxygen were exposed to light for five months (from December 9 to May 26); the amount of free and combined chlorine was then determined (the details are given in Table I.). It will be seen that in bulbs 1, 2 the percentage of free chlorine is only 3.6 to 3.4, rising suddenly, however, in bulb 3 to 92.5 per cent.; in No. 4 the amount of chlorine liberated reaches the maximum, viz., 92.77 per cent.; when more oxygen is added the percentage of liberated chlorine is lowered, the effect being probably to dilute the hydrochloric acid gas. The next series consisted of bulbs similarly prepared, but exposed for sixty-nine days (from May 31 to August 7). From the analysis given in Table II. it will be seen that oxidation of the acid has taken place, even in presence of a small excess of oxygen; in many cases the whole of the acid has been oxidised to chlorine and water, and in some cases hypochlorous acid (or some other oxygen acid of chlorine) has been formed; this accounts for the percentage amount of free chlorine coming out too high.

It appears probable that the oxidation takes place in two stages, the first action of light being to oxidise part of the hydrochloric acid to hypochlorous acid: this is at first decomposed into chlorine and water by the excess of acid present, as is shown in the first series; but when the greater part of the hydrochloric acid has been removed the hypochlorous acid does not further suffer decomposition.

Rate at which oxidation takes place.—When gaseous hydrochloric acid and oxygen are first exposed to light the decomposition goes on with extreme slowness; it rapidly increases, however, with the amount of chlorine liberated. An experiment was made on this point in which a tube containing hydrochloric acid and oxygen was exposed to light together with a tube containing a similar mixture, which had, however, been previously exposed to light until 92.6 per cent. of free chlorine had been set free; when the chlorine was estimated in the two bulbs it was found that the first bulb contained 0.9 per cent. free chlorine, whereas the other tube had gained 7 per cent., making a total of 99 per cent. free chlorine.

Influence of free chlorine.—Experiments were made to determine what influence free chlorine had on the decomposition of the acid. For this

purpose four bulbs were filled with a mixture of hydrochloric acid and oxygen; a known quantity of chlorine was added to three of them. The four bulbs were exposed for the same length of time and the chlorine was then estimated, when it was found that the mixture to which no free chlorine had been added contained 75.9 per cent. free chlorine, whilst the bulbs containing free chlorine in the first instance gave 100.93, 105.37, and 87.29 per cent. of free chlorine. Further experiments are being made in this direction; it appears, however, likely that the presence of chlorine renders the mixture less transparent to those rays which promote the oxidation of the acid.

Influence of bromine.—A weighed quantity of bromine was added to a mixture of hydrochloric acid and oxygen, and exposed in bulbs, together with those just described; when the gas was analysed it was found that only 10.85 per cent. of chlorine had been liberated in one bulb, and 5.05 per cent. in the other (the latter contained a larger quantity of bromine). It does not appear likely that this retarding action of the bromine can be due to its union with the chlorine liberated in the presence of excess of hydrochloric acid, and it will be interesting to observe the influence of bromine vapour on the oxidation of hydrobromic acid.

Influence of moisture.—It has already been stated that a mixture of dry hydrochloric acid and oxygen is unacted on in sunlight, and it was at first supposed that the partially dry mixture was completely stable in the light; it has, however, been found that a very prolonged exposure brings about slow oxidation, the rate depending on the amount of moisture present. The results obtained after four months' exposure show that when two-thirds of the gas was dried 23.6 per cent. of chlorine is set free; when one-third only of the gas was dried 42.8 per cent. is liberated; in the case of both gases saturated, as nearly as possible, 88 per cent. of chlorine is liberated.

Decomposition of chlorine water.—Experiments have been made on the action of light on chlorine water and chlorine and aqueous vapour; the results given on Table III. show that the amount of decomposition increases with the volume of water taken; the ultimate strength of acid, however, varies in each case, becoming more concentrated as the volume of water taken diminishes. On the other hand, the volume of oxygen set free diminishes with the water. With a dilute solution of chlorine water the decomposition is arrested by a comparatively large volume of oxygen acting on a weak solution of acid; with a strong solution a small volume of oxygen is tending to decompose a concentrated acid. These results can be represented graphically in the form of a curve by mapping the percentage of combined chlorine found after exposure against the volume of water taken.

Chlorine gas and water vapour.—A known volume of carbon dioxide saturated with water vapour was mixed with enough chlorine to theoretically decompose all the water; after exposure for thirty-three days 1.33 per cent. of chlorine had been converted into hydrochloric acid. In a second experiment oxygen was substituted for carbon dioxide. In this case 3 per cent. of chlorine was found to be present as chloride.

Further experiments are being made in which a large volume of moist gas is taken, the gas being only partially saturated, as it is possible that condensation took place on the sides of the flask.

Some preliminary experiments have been made with chlorine water exposed to light in coloured solutions. From these it appears that decom-

position takes place in rays considerably below the blue. How far this is due to heating effect has yet to be proved; an apparatus is being prepared to study with greater accuracy the influence of different parts of the spectrum on chlorine water and on hydrochloric acid and oxygen.

The influence of oxygen on a mixture of chlorine and hydrogen has been observed; the gases were exposed for periods varying from three hours to three days. At first it was found that, with increased exposure, the amount of free chlorine was reduced; but when all the hydrogen present had been converted into hydrochloric acid the green colour of the chlorine gradually returned, owing to the slow decomposition of the acid by the oxygen. Analysis gave—

After three hours' exposure, 41.2 per cent. free chlorine.

„ seven „	6.29	„	„
„ two days' „	20.3	„	„
„ three „	31.9	„	„

Little has been done on the oxidation of the other halogens. We hope, however, to be able to report on these when the Association meets next year.

TABLE I.—*Decomposition of Gaseous Hydrochloric Acid and Oxygen in Sunlight after 170 days' exposure, from December 9 to May 26.*

No. of Bulb	Proportion of HCl to O by Volume	Weight in Grams of Free Cl	Weight in Grams of Total Cl	Percentage Free Cl	Percentage Combined Cl

Second Report of the Committee, consisting of Professors TILDEN and RAMSAY and Dr. NICOL (Secretary), appointed for the purpose of investigating the Nature of Solution.

The mutual solubility of salts which do not act chemically on one another.

WHILE it has been long known that the presence of one salt greatly influences the solubility of another salt dissolved in the same mass of water, nothing is known of the laws regulating this phenomenon. Much of our ignorance on this point is doubtless due to the difficulties attending the determination of solubility in general, but more to the fact that experimenters have confined themselves to the task of ascertaining the effect of one salt on another when both are dissolved simultaneously to saturation.

An extended series of experiments has been made on the following lines:—

Solutions containing definite quantities of one salt have been prepared and a second salt dissolved to saturation in these. Thus solutions containing 2, 4, and 6 molecules of NaCl in $100\text{H}_2\text{O}$ were prepared and KCl was dissolved to saturation in these, a special apparatus being employed by means of which complete saturation was ensured without any loss of water by evaporation. Similar converse experiments were made with KCl solutions in which NaCl was dissolved and in all the mutual action of the following pairs was examined:

- | | |
|----------------------------|--------------------------------------|
| 1. NaCl in KCl | 5. KCl in KNO_3 |
| 2. KCl in NaCl | 6. KNO_3 in KCl |
| 3. NaCl in NaNO_3 | 7. NaNO_3 in KNO_3 |
| 4. NaNO_3 in NaCl | 8. KNO_3 in NaNO_3 |

In addition the densities of mixtures of the above salts in various definite proportions up to near the saturation point were determined, and also the mutual solubility to saturation of both members of each pair.

Time has not permitted us to complete the working out of the data thus obtained, but the general results may be stated as follows:—

In the first six cases the solubility of the first salt is diminished by the presence of the second when compared with the solubility in pure water. But if each salt is assumed to have its proportionate share of the water present then the solubility of both salts is increased.

In pair 7 the solubility of NaNO_3 is increased by the presence of KNO_3 , while in pair 8 the presence of a small quantity of NaNO_3 diminishes the solubility of KNO_3 , but a larger quantity increases it. Whether or not this anomalous behaviour is due to the isodimorphism of the two salts, as has been already suggested,¹ further experiments alone will show; but it may be here noted that the rhombic form of KNO_3 is much more soluble than the ordinary prismatic form, as is easily proved by allowing a drop of potassium nitrate to evaporate slowly on a glass plate and after rhombic crystals have separated, on touching the drop with a wire, instant crystallisation in the prismatic form results. This also is one of the few instances, if not the only one, of supersaturation in the case

¹ Nicol, *Phil. Mag.*, June 1884.

of a salt crystallising without water, and the dimorphism, and consequent supersaturation, lends support to the view that supersaturation is due to the fact that the individual in solution differs from that which crystallises out.

Solubility of salts in aqueous solutions of alcohol.

That salts are less soluble in alcohol than in water has been shown by the experiments of Schiff and Girardin, but hitherto the attempts to trace out the connection between the solubility and the amount of alcohol present have entirely failed.

A series of experiments on this subject has been commenced and considerable progress has been made towards completion. The method of experiment is as follows: Solutions of alcohol of definite strengths are prepared by diluting absolute alcohol with weighed quantities of water. The composition of the solutions thus obtained is checked by a comparison of their densities with the table given by Mendeléef; 10 to 15 cc. of these solutions, which are of definite molecular strength (5, 10, 15, &c., molecules of alcohol to $100\text{H}_2\text{O}$), are placed with excess of salt in the saturation apparatus referred to above, and after 24 hours, during which time the contents of the tubes have been shaken 20,000 times, the clear solution is poured off, evaporated to dryness, and weighed.

The salts suitable for these experiments are few in number. No hydrated salts can be used and the anhydrous salts must be freely soluble in water, otherwise their solubility in dilute alcohol sinks so low that the experimental error becomes too high.

Up to the present only four salts have been examined, NaCl , KCl , NaNO_3 , and KNO_3 , in four solutions of alcohol up to 20 molecules, but the densities of solutions of these salts in the alcohol solutions have also been determined. The results have yet to be worked out.

The Committee propose to complete the experiments in these two branches of the subject and then turn their attention to the vapour-pressures of water from solutions, the special apparatus for which has been long ready. With this view they desire to be appointed for another year.

Report of the Committee, consisting of Professor RAY LANKESTER Mr. P. L. SCLATER, Professor M. FOSTER, Mr. A. SEDGWICK, Mr. WALTER HEAPE, Professor A. C. HADDON, Professor MOSELEY, and Mr. PERCY SLADEN (Secretary), appointed for the purpose of making arrangements for assisting the Marine Biological Association Laboratory at Plymouth.

YOUR Committee have the pleasure to report that on June 30 last the laboratory and tanks of the Marine Biological Association at Plymouth were formally declared open and ready for work.

Immediately afterwards Mr. Cunningham, Mr. Weldon, and Mr. Bourne, assisted by Mr. Garstang, secretary to the Director, began to explore methodically that part of Plymouth Sound lying within the breakwater. The results of the exploration are not yet ready for publi-

cation, but it has proved that the fauna lying inside the breakwater is poor in comparison with that outside.

Mr. Cunningham has continued his special investigations upon the development of teleostean fishes.

Mr. Weldon has continued his work on Crustacea with special regard to the development of *Homarus* and *Palinurus*.

Mr. Bourne has devoted some time to an examination of the Hydroidea of the district.

Mr. Garstang is working out the Mollusca.

Mr. Hardy, of Caius College, Cambridge, arrived at the laboratory in July, and at once commenced an investigation upon the development of sponges (*Asconidæ*), which is proceeding. During the month of August Mr. Beddard has been investigating the marine oligochæte worms of the district, and Dr. C. A. MacMunn has been engaged in investigating the colouring matter of various marine invertebrates. Dr. Burdon Sanderson and Mr. Gotch are expected during September, and will continue their investigations on the electric organs of skates and rays.

Although the buildings are practically ready, and can be used for research, some delays and hindrances have occurred in the stocking of the aquarium attached to the laboratory, and the want of certain fittings, now supplied, has hindered the staff in making a complete collection of the fauna of the district.

At present Mr. Bourne and Mr. Weldon are making a series of observations with the surface-net, principally by night, with the view of gaining accurate knowledge of the pelagic fauna of the Channel.

It has been found that the work of the Association has been sadly hampered by the want of a small but seaworthy steamboat, such as the Naples steamboat 'Johannes Müller.' The Association does all its present work with a small hook-and-line boat of about five tons, and it is found that in calms, rough weather, and contrary winds much time is wasted. It is also a great disadvantage that the trawl or dredge has to be hauled in by hand, an operation which could be performed by a small steam winch on a steamboat. The Council of the Biological Association has authorised the Director to make a special appeal for funds towards purchasing and maintaining such a steamboat, and should the General Committee of the British Association be prepared to make a further grant towards the Plymouth laboratory, your Committee would venture to suggest that it should take the form of a donation to this special fund.

Your Committee have paid to the Marine Biological Association the sum of 100l., placed at their disposal for that purpose; and the Council of the Biological Association have tendered to your Committee their thanks for the support given to the Biological Association by the Council of the British Association.

Your Committee beg to point out that it would, in their opinion, be desirable for the Council of the British Association to complete its contributions to the Marine Biological Association to the total of 500l., and thus acquire the power of nominating a life governor of the Marine Biological Association.

Third Report of the Committee, consisting of Professors TILDEN and ARMSTRONG (Secretary), appointed for the purpose of investigating Isomeric Naphthalene Derivatives. (Drawn up by Professor ARMSTRONG.)

THE following is an outline of the work accomplished during the past year in the reporter's laboratory chiefly with the invaluable co-operation of Mr. W. P. Wynne, B.Sc.

In discussing the laws of substitution for naphthalene, attention was directed in the first report to the *alpha* law as the dominant law; and it was pointed out that whenever departures from this law occur, as a rule, either the conditions are such as to favour secondary changes—as in the formation of β -sulphonic acids at high temperatures in presence of an excess of sulphuric acid—or a radicle such as OH or NH_2 is present which exercises a special influence. It was mentioned, however, in the same report, that when β -chloronaphthalene is sulphonated by means of SO_3HCl , two isomeric acids are formed which there is reason to believe are represented by the formulæ:—

The conditions are such that the formation of the β -acid cannot be attributed to the occurrence of secondary changes such as in all probability take place when sulphuric acid is the agent; the production of this derivative, therefore, cannot well be reconciled with the *alpha* law, but is suggestive of the existence in the naphthalene molecule of a 'plane of symmetry' passing through the $\beta^2\beta^{3'}$ -carbon atoms in which an influence is exercised. The observations on isomeric change briefly described in the last report prompted us, however, to determine whether the α -acid could not readily be converted into the β -acid by heating: the results entirely favour the view that the latter acid is in reality the product of isomeric change, and that its formation is in no way an exception to the *alpha*-law. When the sulphonation was effected in the cold, only three to four per cent. of the product consisted of the β -acid; after heating the product at 100° for half an hour the amount rose to eleven per cent.; heating at 150° for one hour increased the proportion of β -acid to twenty per cent.; and no less than fifty-three per cent. was present after heating at 150° for five hours.

These results have led us to study the behaviour of the chloronaphthalenesulphonic acids generally when heated, in order to determine whether, and in what way, they undergo isomeric change. In preparing the necessary material for these experiments we have converted the four isomeric modifications of betanaphthylaminesulphonic acid by Sandmeyer's method into the corresponding chloronaphthalenesulphonic acids, and by distilling these with phosphorus pentachloride have prepared the corresponding dichloronaphthalenes. The designation of the amido-acid, the

melting-point of the sulphochloride of the chloro-acid, and the designation and melting-point of the dichloronaphthalene are as follows:—

	Sulphochloride	Dichloronaphthalene
	m. p.	m. p.
betanaphthylaminesulphonic acid (α) (Badische) .	129°	(θ') 63°·5
" " (β) (Brönner) .	109°	(ϵ) 135°
" " (γ) (Dahl) .	70°	(η) 48°
" " (δ) (Bayer and Duisberg)	86°	(δ) 114°

Isomeric dichloronaphthalenes.—No less than 12 isomeric dichloronaphthalenes have now been described. The conventional plane symbol of naphthalene serves to exhibit only ten, but a geometrical symbol may be constructed in accordance with the method followed by Herrmann in the case of benzene ('Berichte,' 1888, 1949), which foreshadows no less than sixteen. The following is a list of the reputed dichloronaphthalenes:—

(1) . . . m.p. = 34°	(7) . . . ζ . . . m.p. = 83°
(2) . . . α . . . m.p. = 38°	(8) . . . κ . . . m.p. = 94°
(3) . . . η . . . m.p. = 48°	(9) . . . γ . . . m.p. = 107°
(4) . . . θ . . . m.p. = 61°·5	(10) . . . δ . . . m.p. = 114°
(5) . . . θ' . . . m.p. = 65°	(11) . . . ι . . . m.p. = 120°
(6) . . . β . . . m.p. = 68°	(12) . . . ϵ . . . m.p. = 135°

α - α -dichloronaphthalenes. Nos. 6, 7, and 9 in the list belong to this category and represent the three possible α - α -derivatives: β -dichloronaphthalene is undoubtedly the $\alpha^1:\alpha^4$ homonuclear modification, being obtainable from naphthalene tetrachloride and from naphthionic acid; γ - and ζ -dichloronaphthalenes are heteronuclear compounds, and if no other evidence were forthcoming, the fact that the γ -compound has the higher melting-point would alone justify us in regarding it as the symmetrical $\alpha^1:\alpha^4$ derivative; since, however, it is obtainable from the nitrosulphonic acid isomeric with the α - α -acid known as the Schölkopf acid, which—taking Bamberger's researches into account—is a so-called *peri* or hetero-ortho derivative, there cannot be any doubt that γ - is 1 : 4' and that ζ is 1 : 1' dichloronaphthalene.

β - β -dichloronaphthalenes.—Of the three possible β - β -modifications, δ - and ϵ -dichloronaphthalene are the two possible hetero-compounds; and from the high melting-point of the latter there can be practically no doubt that it is the symmetrical 2 : 3' modification, the δ -compound being therefore the 2 : 2' derivative.

α - β -dichloronaphthalenes.—Four are possible, two hetero- and two homonuclear. η - and θ' (m.p. 63°·5) dichloronaphthalenes may be prepared as above stated from Dahl's and the Badische modification of betanaphthylaminesulphonic acid respectively, and also from two α -nitro-acids obtained by Cleve by nitrating naphthalenebetasulphonic acid; they are therefore undoubtedly α - β -compounds, and are probably both heteronuclear. If these arguments be correct, the one is 1 : 2', the other 1 : 3' dichloronaphthalene.

θ -dichloronaphthalene (m.p. 61°·5) is either the 1 : 2 or the 1 : 3 modification. α -dichloronaphthalene, the product of the action of alkali on naphthalene tetrachloride, is undoubtedly a homonuclear compound. The modification melting at 34°, prepared by Cleve from chlorobetanaphthol and chlorobetanaphthylamine, is also homonuclear; this latter is an *alpha*-chloronaphthalene derivative (Cleve), so that the dichloronaphthalene melting at 34° if not the 1 : 2 is the 1 : 3 variety. By exclusion, it

would follow that α -dichloronaphthalene is the third β - β -, i.e., β^2 - β^3 -dichloronaphthalene.

κ and ι -dichloronaphthalenes have thus far been omitted from consideration; the former is probably non-existent, the method by which it is said to have been prepared being one which is very unlikely to afford a dichloronaphthalene. It is not improbable that the ι -compound will also be found non-existent: if on treating naphthalene with chlorine a small quantity of an isomeric heteronuclear tetrachloride be formed, and this lose its α -chlorine atoms, ϵ -dichloronaphthalene would result, and it is possible that this substance in an impure state may have been regarded by mistake as a distinct substance.

Isomeric dichloronaphthalenesulphonic acids.—With the object of further characterising and determining the individuality of the dichloronaphthalenes, the study of their sulphonic acids, to which reference was made in the last report, has now been extended to all. The chief result of interest is the fact that the dichloronaphthalene melting at 34° yields certainly two, perhaps three, isomeric sulphonic acids; the sulphochloride of the one acid crystallises in minute prisms melting at 168° , that of the other in massive prisms melting at 105° .

The dichloro-acids prepared by Widman by chlorinating naphthalene- α - and β -sulphochlorides have also been examined. That from the β -sulphochloride yields when hydrolysed β -, that from the α -sulphochloride what appears to be θ -dichloronaphthalene, m.p. $61^\circ.5$.

Addendum.—Since the meeting of the Association, Erdmann and Kirchhoff ('Annalen,' 247, 366) have described the results of experiments on the synthetic production of chloronaphthalene derivatives which they contend afford proof of the constitution of the γ , η and θ varieties of dichloronaphthalene. Their method consists in preparing chlorophenylparaconic acids by interaction of succinic acid and chlorobenzaldehydes; by distilling the acids, chloronaphthols are obtained from which corresponding dichloronaphthalenes are prepared by distillation with phosphorus pentachloride. The conversion of phenylparaconic acid itself into alphanaphthol is supposed by Fittig and Erdmann to take place in the manner indicated by the following symbols:

Assuming that the chloro-acids undergo a similar change, the acids derived from ortho- and parachlorobenzaldehyde should each yield but a single chloronaphthol, and that from the metachlor-aldehyde should alone be capable of yielding two isomers, viz.:—

Actually they obtained eventually from the metachloro-acid η -dichloronaphthalene (m.p. 48°); and as ζ -dichloronaphthalene (m.p. 83°) is undoubtedly the $1 : 1'$ derivative, they regard the η as the $1 : 3'$ derivative. The orthochloro-acid was found to yield γ -dichloronaphthalene, and hence they regard this as the $1 : 4'$ derivative—a conclusion which harmonises with previous views. θ -dichloronaphthalene (m.p. $61^\circ.5$) was prepared from the parachloro-acid, and accordingly this is represented to be the $1 : 2'$ derivative.

But these conclusions are entirely based on the assumption that the naphthol-hydroxyl is derived from one of the carboxyl groups of the succinic acid, as indicated by the symbols given above: there is, however, no reason why it should not be derived from the COH group of the aldehyde, and in this case the η would be the $1 : 2'$ and the θ the $1 : 3'$ derivative. In any case, this objection entirely deprives Erdmann and Kirchhoff's arguments of their force: as in the case of benzene, there is little doubt that the constitution of naphthalene derivatives will be determined eventually by the study of naphthalene derivatives and not by synthetic methods of the character of those in question.

Third Report of the Committee, consisting of Dr. GARSON, Mr. PENGELLY, Mr. F. W. RUDLER, Mr. G. W. BLOXAM (Secretary), Mr. J. THEODORE BENT, and Mr. J. STUART GLENNIE, appointed for the purpose of investigating the Prehistoric Race in the Greek Islands.

THIS spring Mr. Bent commenced researches on the promontories jutting into the Ægean Sea along the coast of Asia Minor. On the most southern of these, opposite the island of Rhodes, was discovered near the ancient Corymba, which was identified by Leake, a curious little harbour, and near it the ruins of a town. After working here for two days, from inscriptions on tombs and the sites of temples, it was identified as having anciently been called Kasarea, or, as Ptolemy and Pliny respectively call it, *Κρησσα λιμὴν* and Portus Cressa.

Proceeding eastwards, on a promontory to the west of the Gulf of Makri, he found the ruins of another hitherto unknown town. Here he was able to work for many days and found much of interest, including 33 inscriptions, which informed him that this town was anciently Lydæ,

an important city of Lycia and the seat of a Roman proconsul. From these inscriptions much was gathered concerning the local government, its division into *demes*, the gods here worshipped, and the names of its chief families and benefactors.

About five miles inland, buried in a forest, he further identified the ruins of another town called Lissæ, and found two inscriptions of the date of the third century B.C., many tombs, and sites of buildings. Over one of the rock-cut tombs in this neighbourhood was found an inscription which appears to be a mixture of Lycian and some other language in use in this district, but which has not yet been deciphered.

The inhabitants of this district are all nomad and form an interesting subject for study. The difficulty of approaching them arising from their suspicion of strangers was only overcome after a few days' residence among them. It would appear that they are almost entirely self-governed, owning allegiance to the *ak-sakal* or white beard who dwells up in the mountains, whilst they wander from one pasturage to another, dwelling in huts and acting as woodcutters. Each division of a tribe is called a *yaela*, with its chief Yuruk Agha-si. Some few become sedentary and till the ground, others wander from place to place for pasturage. Mr. Bent hopes to return to these parts next winter and to make further investigations amongst them.

The things found during Mr. Bent's excavations are now deposited in the British Museum.

The Committee ask for reappointment with enlarged powers, and that the grant may be increased to 40l.

Report of the Committee, consisting of Sir RAWSON RAWSON, General PITT-RIVERS, Dr. MUIRHEAD, Mr. C. ROBERTS, Dr. J. BEDDOE, Mr. H. H. HOWORTH, Mr. F. W. RUDLER, Dr. G. W. HAMBLETON, Mr. HORACE DARWIN, Mr. G. W. BLOXAM, Dr. GARSON, and Dr. A. M. PATERSON, appointed for the purpose of investigating the effects of different occupations and employments on the Physical Development of the Human Body.

THE Committee met frequently during the past year. A circular has been issued asking for the active assistance of employers of labour and others who have access to large bodies of working men, and the Committee has received many promises of assistance.

Cards for recording observations have been printed, and a paper of instructions to ensure, as far as possible, uniformity in taking the observations has been drawn up.

It has been resolved to confine the operations of the Committee to one large centre of population at a time, and Manchester has been selected as a starting point. A sub-committee has been formed there, and the Committee anticipate valuable results during the ensuing winter, but no returns have yet been received.

The Committee respectfully ask for reappointment and for a renewal of the grant.

Sixteenth Report of the Committee, consisting of Professors J. PRESTWICH, W. BOYD DAWKINS, T. MCK. HUGHES, and T. G. BONNEY, Dr. H. W. CROSSKEY, and Messrs. C. E. DE RANCE, H. G. FORDHAM, D. MACKINTOSH, W. PENGELLY, J. PLANT, and R. H. TIDDEMAN, appointed for the purpose of recording the position, height above the sea, lithological characters, size, and origin of the Erratic Blocks of England, Wales, and Ireland, reporting other matters of interest connected with the same, and taking measures for their preservation. (Drawn up by Dr. CROSSKEY, Secretary.)

It was expected that this Committee would be able at an early date to summarise and conclude its reports; but as its existence and object are becoming more generally known, so large a number of new observations are being forwarded, that it is necessary that its work should still be carried on.

Among the important points that are being brought to light are: (1) the very distinct grouping of erratics in various localities, showing clearly that they have travelled in definitely marked courses; (2) the determination of the character of these groups by the physical geography of the country—ridges of existing highlands and hills effectually stopping or diverting the courses of the streams of boulders; (3) the occasional crossing of the groups of boulders—the meeting places of different streams being determinable; (4) the deposition of erratics at different periods.

When the summary of the reports is prepared, these facts will be found to stand out with great clearness and their bearing upon the glacial theories will prove to be of large importance.

YORKSHIRE.

Very remarkable facts were recorded in last year's report, respecting the boulders in the parish of Ingleby Greenhow, Northallerton; where blocks from the Lake district, from the S.W. of Scotland, from the Cheviot hills and adjoining districts, from more distant northern parts of Scotland, are intermixed with glaciated blocks of local origin.

The Rev. John Hawell supplements the information previously given and has examined 365 boulders (Professor Bonney and Mr. C. T. Clough giving their kind assistance in the determination of some of the specimens) with the following results:—

(1) Shap granite	3
(2) Granite of Criffel type	1
(3) Dolerites	9
(4) Syenite or diorite (Scotch)	1
(5) Quartzite	1
(6) Quartzose rock	1
(7) Quartzose greywacke	1
(8) Vein quartz	1
(9) Quartz-felsite (from St. John's Vale?)	2
(10) Felsite	1
(11) Porphyrites from Cheviots	67
(12) Porphyrites from Cheviots or S. Scotland	7

(13) Porphyrite (from near Kelso ?).	1
(14) Porphyrite from Cheviots or near Kelso	1
(15) Felsite or porphyrite (Scotch).	1
(16) Hornblendic porphyrite	1
(17) Hornblendic felsite or porphyrite	1
(18) Porphyrites from Borrowdale series	4
(19) Augite-andesites from Cheviots	2
(20) Old augite-andesites	2
(21) Augite-andesites from Cleveland Dyke	57
(22) Doubtfully from the Cleveland Dyke	1
(23) Basalt of uncertain derivation	4
(24) Basalt or augitic andesite	1
(25) Very compact basalt (Scotch)	3
(26) Porphyritic basalt (from Carter Fell ?)	3
(27) Indurated volcanic ashes from Borrowdale series	13
(28) Felstones from Borrowdale series	7
(29) Doubtfully felstones from Borrowdale series	3
(30) Felstone ?	1
(31) Hälleflinta?	1
(32) Sandstones from local Inferior Oolite	81
(33) Sandstones, Oolitic and otherwise	11
(34) Coarse grits	11
(35) Millstone grits	2
(36) Fine quartz grit	1
(37) Calciferous sandstone	1
(38) Argillaceous limestone	1
(39) Calcareous cherty limestones	2
(40) Limestones	38
(41) Mudstones	4
(42) Brown calcareous rock	1
(43) Of uncertain character	4
(44) Notes too imperfect, or specimens mislaid	6
Total	365

(1) No. 234—In stream below Ingleby Mill Dam; rounded; $33 \times 21 \times 18$ in. No. 306—In Mr. H. Bainbridge's field; Greenhow; rounded; $15 \times 13 \times 10$ in. No. 328—Near Mr. H. Bainbridge's house; in stream; rounded; $22 \times 18 \times 16$ in.

(2) In bed of stream below Ingleby Manor House; rounded; diameter about 18 in.

(3) The dolerites may not improbably have been derived from the Whin Sill of Teesdale. Mr. Clough, however, says, 'The Whin Sill also occurs with much the same character in parts of Weardale, Northumberland, and there are also various dykes in N. of England of same character.' No. 243—In Ingleby Mill Dam; imperfectly rounded; $19 \times 16 \times 14$ in. No. 265—By side of railway near Mr. Gill's farm; rounded; $27 \times 22 \times 13$ in. No. 364—On Kirby-Moorside Road, above Bank*Foot; rounded; $22 \times 20 \times 13$ in.

(4) No. 349—In stream below Ingleby Manor; subangular; $8 \times 6 \times 6$ in. 'Syenite or Diorite—Scotch' (Bonney). 'Might be from the shoulder of Criffel' (Clough).

(5) No. 268—In Mr. Gill's field; well rounded; $6 \times 5 \times 4$ in. 'Quartzite; possibly derived from an Old Red Conglomerate' (Bonney).

(6) No. 39—Ingleby Vicarage Garden; rounded; $13 \times 11 \times 10$ in.

(7) No. 176—Ingleby Mill Dam; rounded; $? \times 6 \times 6$ in. 'Quartzose Greywacke—probably S. Scotch' (Bonney).

(8) No. 352—Stream below Ingleby Mill Dam; rounded; $20 \times 16 \times 13$ in. 'Vein quartz—Chalcedonic' (Bonney).

(9) No. 98—Ingleby Mill Dam; hard, subangular; $13 \times 12 \times 6$ in. No. 158—Ingleby Mill Dam; angular; $? \times 7 \times 5$ in. 'Felsite or porphyrite (Bonney). These blocks may not improbably have been derived from the quartz-felsite of St. John's Vale, Cumberland.

(10) No. 93—Ingleby Mill Dam; subangular; $8 \times 4 \times 3$ in.

(11) No. 125—Ingleby Mill Dam; subangular; $17 \times 8 \times ?$ in. 'Porphyrite—old andesite (Cheviot?)' (Bonney). 'Possibly from the Cheviots, but not a common type there, and should think more probably from some of the porphyritic areas in the S. of Scotland' (Clough). No. 138—Ingleby Mill Dam; moderately rounded; $24 \times 15 \times ?$ in. No. 139—Ingleby Mill Dam; subangular; $21 \times 18 \times 10$ in. The above are some of the largest of these common blocks which so strongly characterise our local drift.

(13) No. 339—On right bank of stream below Ingleby Mill Dam; subangular; $16 \times ? \times 14$ in. 'Porphyrite—probably an old andesite' (Bonney). 'Very like some of the upper Old Red traps of the neighbourhood of Kelso. I have also noticed these rocks mixed with Cheviot rocks in considerable quantities in Bridlington Bay boulders' (Clough).

(14) No. 232—Ingleby Mill Dam; angular; $8 \times 7 \times 5$ in. 'Might well be from the Lower Old Red porphyritic district of the Cheviot Hills' (Clough).

(15) No. 275—In Mr. Gill's field, Ingleby; subangular; smoothed; $4 \times 8 \times 6$ in. 'Felsite or porphyrite—Scotch' (Bonney).

(16) No. 303—In stream below Ingleby Mill Dam; subangular; $10 \times 6 \times 6$ in. 'Hornblendic porphyrite—S. Scotland' (Bonney). 'Not unlike portions of the lowest of the porphyritic flows at the head of Coquetdale, Cheviot Hills' (Clough).

(17) No. 319—In stream near Mr. H. Bainbridge's farm, Greenhow; rounded; $21 \times 17 \times 14$ in. 'Hornblendic felsite or porphyrite' (Bonney). 'Very like some igneous masses in the Highlands near the head of Loch Katrine, Loch Lomond, &c.' (Clough).

(18) The largest of these is No. 302. In stream below Ingleby Mill Dam; subangular; $17 \times 10 \times 6$ in.

(21) As the Cleveland Dyke at its nearest point, near the village of Great Ayton, is distant only some four miles from the present position of the boulders to which these notes refer, and as the ice-sheet must have ploughed across it almost at right angles in the immediate direction of our locality, we should naturally expect to find what, in point of fact, we do find—numerous angular and subangular fragments derived from it, intermixed with the other boulders. The 'Whinstone,' as it is locally termed, is described in the memoir of the Geological Survey relating to the district as 'a bluish-grey augite-andesite, consisting of a ground mass apparently made up of augitic and felsitic matter, with small crystals of felspar and augite. Scattered through this are glassy crystals of triclinic felspar of much larger size, very distinctly visible to the unaided eye, and which give the rock a distinctive character by which it can be easily recognised.' As other dykes of a very similar character occur in the direction from which the ice-sheet came, it is possible that one or two from other sources may have been put down as from this source. The largest measures $48 \times 35 \times 34$ in. Others measure respectively 39 in., 33 in., 29 in., 28 in., 27 in. in their longest diameter.

(22) No. 113—Ingleby Mill Dam; imperfectly rounded, with smooth faces: $11 \times 8 \times 6$ in.

(24) No. 274—In Mr. Gill's field; moderately rounded; $13 \times 9 \times 7$ in. 'Basalt or augitic andesite—Northern' (Bonney).

(26) 'Porphyritic basalt—Scotch or north of England' (Bonney). 'Looks as if it might be from the porphyritic basalt rock of Lumsden Law or the Carter Fell or from some other of the similar basaltic rocks of the Border country' (Clough).

(27) Two in Greenhow measure respectively $31 \times 20 \times 13$ in. and $27 \times 17 \times ?$ in.

(28) The largest of these measures $13 \times 12 \times 10$ in.

(29) A subangular boulder at Ingleby Mill Dam measures $18 \times 13 \times 7$ in.

(30) No. 326—In Mr. H. Bainbridge's field, Greenhow; rounded; $10 \times 6 \times 4$ in.

(31) No. 73—By side of road near Ingleby Church; imperfectly rounded; hard; green; $14 \times 9 \times 5$ in. 'Not igneous—a Hälleflinta' (Bonney). 'Should strongly suppose this to be one of the rocks of the volcanic series of Borrowdale' (Clough).

(32) The real proportion of these blocks is somewhat higher than is represented by the number 81, since some small ones have been passed over where more unfamiliar rocks would have been noted. The following are the measurements of a few of the largest: $36 \times 20 \times 17$ in.; $33 \times 18 \times 12$ in.; $30 \times 22 \times ?$ in.; $29 \times 14 \times ?$ in.; $29 \times ? \times 12$ in.; $24 \times ? \times 16$ in.; $23 \times 22 \times 14$ in. The majority of the above consist of a somewhat compact sandstone, not easily worn and resisting decomposition.

(33) Some of these are probably from the Oolite; others from the Carboniferous. The largest measures $16 \times 10 \times 7$ in.

(34) These are probably all from the Inferior Oolite. The largest of them, which is at the Ingleby Mill Dam, measures $29 \times ? \times 8$ in.; others measure $24 \times 17 \times ?$ in.; $23 \times ? \times 19$ in.

(36) No. 150—Ingleby Mill Dam; $6 \times 6 \times 4$ in. 'Fine quartz grit; probably Carboniferous' (Bonney).

(37) No. 145—Ingleby Mill Dam; subangular; $? \times 9 \times 4$ in.

(38) No. 351—In stream below Mill Dam; subangular; $22 \times 19 \times ?$ in.; argillaceous limestone: perhaps from the Oolite.

(39) No. 166—Ingleby Mill Dam; subangular; $17 \times ? \times 10$ in. No. 299—In stream below Mill Dam; angular; $10 \times 6 \times 4$ in.

(40) The majority, but not all, of these are from the Mountain Limestone. Some are greenish or yellowish; others very light coloured; a few nearly black. No. 165—Ingleby Mill Dam; a flat slab; finely stratified; $28 \times ? \times 5$ in. No. 282—In stream immediately below Mill Dam, having recently fallen from left bank; angular; cubical; ordinary mountain limestone, full of fossils, including *Spirifera bisulcata*, *Syringopora geniculata*, *Athyris ambigua*, *Terebratula vesicularis*, and a shell which I take to be *Spiriferina cristata*, var. *octoplicata*; $22 \times 19 \times 14$ in.

(41) No. 256—Marsh Lane; rounded and flattened; stratified; striated on one side in various directions; $18 \times 14 \times 5$ in. 'Mudstone' (Bonney). No. 48—Ingleby Vicarage Garden; discoidal; $9 \times 7 \times 3$ in. 'Mudstone—Scotch Silurian(?)' (Bonney). 'Very like one of the Coniston flagstones of the English Lake district; probably came over the watershed W. of Bowes with the Shap granite boulders' (Clough).

(42) No. 350—In stream below Ingleby Mill Dam; angular; $1 \times 18 \times 3$ in.

The Committee have received the subjoined valuable reports from the

'Yorkshire Boulder Committee,' formed in connection with the 'Yorkshire Naturalists' Union.'

That Committee have had the advantage of the services of Professor Green, F.R.S., as chairman, and Mr. S. A. Adamson, F.G.S., as secretary, and have examined and passed all the reports which are subjoined.

The Rev. E. M. Cole, M.A., Wetwang, forwards the following reports:—

In a field, about 350 yards north of Gristhorpe station, near Filey, and about 50 yards east of the railway, is an isolated boulder of basalt; sub-angular; 4 ft. 7 in. \times 2 ft. 10 in. \times 1 ft. 11 in. Partially imbedded in ground.

In the North Skengh Field, Stillington, near Easingwold, is a boulder 4 ft. 3 in. \times 3 ft. \times 2 ft. 7 in.; rounded; has not been moved; longest axis N.E. and S.W. No striæ apparent. A very hard cherty limestone. About 150 feet above sea-level. Rests upon Middle Lias.

In and around the village of Muston, near Filey, are the following boulders:—

- No. 1. 3 ft. \times 2 ft. \times 1½ ft., basalt, smoothed.
- „ 2. 1 ft. 3 in. \times 1 ft. 9 in. \times 1 ft. 6 in., basalt, sharp edges.
- „ 3. 2 ft. \times 3 ft. \times 1 ft. 8 in., basalt, smoothed.
- „ 4. 4 ft. 5 in. \times 1 ft. 10 in. \times 2 ft., basalt, triangular-shaped end.
- „ 5. 3 ft. \times 2 ft. 4 in. \times 1 ft. 8 in., basalt, angular.
- „ 6. 1 ft. 8 in. \times 2 ft. 6 in. \times 2 ft. 11 in., basalt, smoothed on one side.
- „ 7. 4 ft. 6 in. \times 1 ft. 7 in. \times 1 ft. 3 in., grit.

Round the sign-post in the centre of Muston village are two boulders: Basalt—2 ft. 7 in. \times 2 ft. 3 in. \times 8 in. (embedded in ground), and 2 ft. 9 in. \times 2 ft. (embedded in ground).

A boulder at the corner of a house close by; basalt, 2 ft. 3 in. \times 1 ft. 8 in. \times 9 in.

There are at least half a dozen others from 1 ft. to 2 ft. cubes.

In a bank, surmounted by a hedge, at the Hunmanby end of the village, are three gritstone boulders: 3 ft. 3 in. \times 1 ft. 8 in. \times 1 ft. 1 in.; 2 ft. 7 in. \times 1 ft. 8 in.; 3 ft. \times 1 ft. 5 in.

In the middle of a grass field, half-way between Muston and Hunmanby, in a straight line, is an isolated boulder of basalt; rounded, 3 ft. 6 in. \times 3 ft. \times 1 ft. 1½ in. Embedded in the ground.

There are two groups of boulders at Bempton and Buckton (East Riding):—

3 ft. \times 2 ft. and 2 ft. cube is the ordinary shape. A few angular, a few sub-angular, but mostly rounded. The stones referred to have all been moved by man, built into foundations of houses, set up at corners of streets; also used as seats. There is no doubt whatever the boulders have been removed from adjacent fields. By far the greater number are whinstone. There are many blocks of various sandstones, but four-fifths are whinstone. 250 feet above sea-level. They are abundant in the villages of Bempton and Buckton. Speaking only of the large ones: 5 may be seen at the well; 10 at the pond close by; 10 more in the cottages towards Cliff Lane; 5 forming steps in the lane itself; hundreds in the walls of smaller size but upwards of 1 ft. cube; 10 in Buckton, upwards of 2 ft.; 15 at least in Old Bridlington at the corner of streets, upwards of 2 ft., some smoothed; 24 by the pond at Flambro', removed thither from adjacent fields.

All the above mentioned are whinstone : it is the characteristic boulder of the Buckton, Bempton, and Flambro' cliffs, and seems ubiquitous.

Two boulders occur at Bempton (E. Riding) in the fields known as 'The Lieys,' a few yards from the top of Bempton Cliffs, opposite Scale Nab; the boulders are about 50 yards apart.

Boulder No. 1.—4 ft. \times 3 ft. \times 1 ft. 6 in. Sub-angular. North, inclined to W. Whinstone. Above sea-level, 275 ft. Isolated.

Boulder No. 2.—4 ft. \times 4 ft. \times 1 ft. 6 in. Sub-angular. Above sea-level, 280 ft. Isolated.

Both rest on a thin boulder clay on chalk.

At Carr Naze, Filey Brigg, are the following erratic blocks :—

1. Rounded block on surface of third field from Filey Church, due north, near cliff, 2 ft. 7 in. \times 2 ft. 5 in. \times 1 ft. 5 in. Whinstone.

2. A similar but flatter block, lying at base of boulder clay, partially exposed, on north side of Naze, just above Oolitic rocks, 2 ft. 11 in. \times 2 ft. 8 in. \times 1 ft. 2 in. Direction E.N.E. Beautifully furrowed with ice-marks. Whinstone.

3. A mass lying exposed on Oolitic rocks, about 50 ft. above sea-level, evidently washed out of boulder clay above, 3 ft. 8 in. \times 2 ft. \times 1 ft. 4 in. Smooth edges, flat surface. Mica trap.

4. Small block, on ledge, fallen as above. Quartz felsite.

5. In boulder clay on S. side of Naze. Black earthy limestone with iron pyrites.

6. Fine mass of Lias, all Lower Lias fossils (*Gryphæa*, *Mya*, &c.), 1 ft. \times 1 ft. 5 in. \times 7 in. Washed out of boulder clay on N. side of the Naze.

7. Mass of freestone lying partially exposed half-way up N. face of boulder clay at Carr Naze, 3 ft. 10 in. \times 2 ft. 4 in. \times 1 ft. Direction N. No markings.

Dr. Carter Mitchell, Topcliffe, Thirsk, reports a boulder of Shap granite in the parish of Cundall, on the Leckby estate, five miles from Boroughbridge, about a quarter of a mile above 'Elmire Ings,' as given on the Ordnance Map. It is in the bed of the river Swale, close to the Leckby bank. It is entirely out of the water when the river is very low; 4 ft. 3 in. \times 3 ft. \times 2 ft. 9 in. Is more or less rounded. No striæ or groovings. Is about 50 ft. above sea-level. There is a long ridge of gravel and sand about a quarter of a mile from where the boulder lies.

Mr. H. M. Platnauer, B.Sc., F.G.S. (Curator of the York Museum), records the following erratic blocks which were obtained from the boulder clay that was dug out when the York new station was built, and are now placed about the grounds of the Philosophical Society of that city :—

1. Shap granite, irregular shape, smooth, 2 ft. 9 in. \times 1 ft. 10 in. \times 1 in.

2. Shap granite, irregular parallelopiped, rough surface, 1 ft. 4 in. \times 1 ft. 4 in. \times 10 in.

3. Shap granite, roughly ellipsoidal, smooth surface, 2 ft. 2 in. \times 1 ft. 1 in. \times 1 ft. 2 in.

4. Shap granite, irregular mass, rounded but not smooth, 3 ft. 1 in. \times 2 ft. 8 in. \times 1 ft. 10 in.

5. Shap granite, irregular oval, smooth, 2 ft. 9 in. \times 1 ft. 10 in. \times 1 ft. 7 in.

6. Whitish limestone, flat piece, polished and striated on one side, 3 ft. \times 1 ft. 3 in. \times 8 in.

7. Estuarine sandstone, rounded mass, 1 ft. 4 in. \times 1 ft. 1 in. \times 9 in.

8. Dark-coloured Mountain limestone, polished and striated, 1 ft. 5 in. \times 1 ft. 2 in. \times 9 in.

9. Limestone (Oolitic, but of what horizon I cannot say), smooth, striated on one side, 1 ft. 4 in. \times 1 ft. 3 in. \times 9 in.

10. Similar to No. 9, 1 ft. 3 in. \times 1 ft. 2 in. \times 7 in.

11. Sandstone (probably estuarine), angular, irregular, 1 ft. 5 in. \times 1 ft. 2 in. \times 1 ft. 1 in.

12. Grey arenaceous limestone (probably Jurassic), irregular, smoothed on one side, 1 ft. 1 in. \times 1 ft. 3 in. \times 10 in.

13. Similar to No. 12, smooth on one side, 1 ft. 8 in. \times 1 ft. 4 in. \times 1 ft. 1 in.

14. Light coloured limestone, smooth, egg-shaped, striated, 2 ft. \times 1 ft. 2 in. \times 1 ft. 6 in.

15. Lithostrotion, small, polished, and rounded mass, 1 ft. \times 9 in. \times 7 in.

16. Greenish-grey trap, probably a hornblende-andesite. An irregular quadrate mass, trapezoidal in section at one direction; the faces at an obtuse angle are polished and somewhat striated, 2 ft. 6 in. \times 2 ft. \times 1 ft. 4 in.

The Rev. Thomas Parkinson, Vicar of North Otterington, near Northallerton, reports as follows:—

In the centre of the village of Thornton-le-Beans, near Northallerton, at the left or north side of the street going eastwards, parish of North Otterington, is a block of Shap granite. Length, 3 ft. 10 in. E. and W. Breadth, 3' 2" N. and S. Above ground 2 ft. 4 in., and probably about the same in the ground. Rounded. Uncertain whether it has been moved or not. Longest axis E. and W. No striæ or groovings. Isolated. Rests on clay.

*In the township of Thornton-le-Moor, parish of North Otterington, are three boulders.

1. In an open field, near a well named 'Stockeld's Well.' About 4 ft. 6 in. \times 2 ft. 8 in. \times 2 ft. 8 in. Somewhat wedge-shaped. Rounded. Cannot say whether it has been moved or not. Longest axis N. and S. (nearly). Granite, ice-worn. Isolated. Rests on clay.

2. In a lane called 'Endecon,' about 300 yards from south end of village of Thornton-le-Moor, 3 ft. 2 in. \times 2 ft. \times 2 ft. Was considerably broken a few years ago. Has been moved. Coarse dolerite. Isolated. Rests on clay.

3. On the roadside, near farmhouse called Hill Top or Thief Hole Farm, 3 ft. 8 in. \times 2 ft. 9 in. \times 2 ft. 9 in., all above ground. Rounded a little, angular in some parts. Has been moved—taken out when foundation was dug of an adjacent building. Close grained trap or highly altered fine ash. Isolated. Rests on clay.

In township of North Otterington, on Otterington Farm, in field near the entrance gate from Northallerton road, and about 300 yards on the road from North Otterington Church; 4 ft. \times by 2 ft. 11 in. Height above ground, one side, 1 ft. 6 in.; the other, 3 to 4 in. Somewhat wedge-shaped. Angles all rounded. Has been moved. There are four ruts running longitudinally on the top and in the direction of longest axis. Granite. Rests on gravel.

Mr. Robert Mortimer, of Fimber, reports that at Youlthorpe, between Bishop Wilton and Stamford Bridge, is a large isolated boulder of pure white very quartzose sandstone. Had not been moved by man until recently, when it was carted into the farmyard of Mr. Hawkins. Is now used as a mounting block. 3 ft. 9 in. \times 2 ft. 9 in. \times 2 ft. 10 in.

Youlthorpe is on the Keuper marl, and not far from the foot of the chalk escarpment of the Wolds.

The Rev. R. A. Summerfield, Vicar of North Stainley, reports that in the parish of North Stainley, near the hamlet of North Leys, and about 100 yards from the 'Smithy' (so marked on the 6 in. Ordnance Map), on the west side of the road to North Stainley, is a block of Carboniferous grit, 3 ft. 3 in. \times 2 ft. 5 in. \times 1 ft. 7 in. Sub-angular. It has been moved from the adjoining field to the place it now occupies about twenty years ago, being a hindrance to ploughing, &c. About 170 ft. above sea-level. Connected probably with a long gravel ridge which abuts on the river bank and underlies all the parish, in which are a large quantity of scratched, grooved, and polished blocks, varying much in size. One block, 5 ft. \times 3 ft. \times 1 ft. 3 in., is a mass of large Producti.

The Rev. Arthur Watts, F.G.S., Vice-Principal of Bede College, Durham, reports that there is a block of encrinital Carboniferous limestone in the grounds of R. L. Hawthorne, Esq., Hawthorne Tower, Seaham Harbour, on north side of Hawthorne Drive and west of the tower. Was removed from an adjacent field when draining to its present position, 5 ft. 10 in. \times 3 ft. 8 in. \times 1 ft. 3 in. Weight, 1 ton 18.79 cwt. Sub-angular. It originally pointed by its long axis 20° E. of N., 42° E. of N. true bearing. There are seven grooves across the stone, five perfect, two imperfect. There are two sets of striæ: the one set of six are nearly obliterated by the other, numbering about seventy. The smaller group of striæ are nearly in the line of the longest axis; the larger group make an angle of about 60° with the long side.

The nearest similar rock known *in situ* is 25 miles due west at Frosterley.

The boulder has no popular name or legend. Is about 80 ft. above sea-level. It was discovered in March 1879, and is not indicated on any map. It formed part of a mass of clay, sand, gravel, and boulders that is seen in a coast section to be in a hollow in the magnesian limestone, about 100 yards wide and 60 ft. or more deep.

Mr. Wm. Gregson, Baldersby, Thirsk, reports upon two boulders in the Priory Grounds, Guisborough, both resting on the Lower Lias.

Boulder No. 1: 4 ft. \times 3 ft. 6 in. \times 1 ft. 3 in. Sub-angular. No groovings or striations. Grey granite 300 ft. above the sea. Isolated. Resting on Lower Lias:

Boulder No. 2: 3 ft. 6 in. \times 3 ft. 2 in. \times 1 ft. Sub-angular. No groovings or striations. Grey granite. 300 ft. above the sea. Isolated. Resting on Lower Lias.

Dr. W. Y. Veitch, Middlesbro', records a Shap-fell granite boulder at Saltburn 30 feet from the top of the road leading up from the beach, almost opposite the Zetland Hotel; 3 ft. 8 in. high, 14 ft. in circumference; is entirely out of ground on one side; rounded; has no long axis, no groovings or striations; has no popular name and is without a legend; about 150 feet above sea-level; is not indicated upon any map. It rests upon Middle Glacial drift.

Mr. C. Brownridge, F.G.S., Leeds, reports on two boulders on the west front of Lindholme Hall, which is about four miles to the S.E. of Hatfield. The hall is upon slightly elevated ground in the centre of Hatfield Chase, a wide extent of bog. The deposits in the vicinity of the hall consist of gravel and sand resting upon Triassic sandstone. The boulders extracted from the gravel include magnesian limestone, Car-

boniferous sandstones of various kinds, gannister and millstone grit, porphyries and basalts, quartzite, vein quartz, black flints, chert, &c.

Boulder No. 1.—1 ft. 10 in. \times 1 ft. 9 in. \times 1 ft. 8 in.; longest axis N.E. to S.W.; sub-angular; Hälleflinta, not unlike some Lake Country rocks in character; no groovings or striations observed.

Boulder No. 2.—2 ft. 11 in. \times 2 ft. 0 $\frac{1}{2}$ in. \times 1 ft. 7 in.; longest axis N.E. to S.W.; rounded; a coarse grit, almost a conglomerate, with large quartz pebbles; no groovings or striations observed.

A mythical personage, half giant, half hermit, known as William of Lindholme, is said to have lived at Lindholme and to have brought the above stones, known traditionally as the 'Thumb Stone' and the 'Little Finger Stone,' to their present position.

Mr. J. W. Davis, F.G.S., Hon. Sec. Yorkshire Geological and Polytechnic Society, furnishes the following note on the groups of boulders at Norber, near Clapham:—

All sizes up to 16 to 20 feet in diameter; angular; slight striations; under surface rarely striated. Rock identical with that of the boulders is found in the valley to the north at various spots, varying from a mile to a mile and a half from the place where the boulders are most thickly congregated. They are composed of Silurian grit and rest on mountain limestone; 800 to 1,250 feet above the sea; area covered is three-fourths of a mile square; several hundreds in number; all exposed on the surface. In many instances the masses of Silurian grit have protected the limestone immediately beneath, whilst the surrounding surface has been removed, and they now stand on pedestals of limestone, 12 to 18 inches in height.

Mr. W. Hodgson Gill, of Stourton, reports the following boulders:—

At Filey, Yorkshire, on the beach behind the wooden piles at the base of cliff, near Ravine Villas, 3 ft. 3 in. \times 2 ft. 2 in. \times 2 ft. 2 in.; is rounded; no groovings or striations; Shap-fell granite; it rests on boulder clay.

At Hunmanby, at the end of the road leading to the beach, 3 ft. 7 in. \times 2 ft. 3 in. \times 2 ft. 3 in.; is sub-angular; no groovings or striations; Shap-fell granite; it rests on boulder clay.

At Filey, on the beach between Primrose Valley and Hunmanby Road; 4 ft. 1 in. \times 2 ft. 9 in. \times 2 ft. 1 in.; angular; no groovings or striations; calcareous sandstone with nodules and pebbles; it rests on boulder clay.

Mr. Samuel Chadwick, Curator of the Malton Museum, sends the following reports:—

In the parish of Cropton, four miles from Pickering, North Riding, and in a grass-field belonging to Mr. James Dixon, Loand House farm, 3 ft. 4 in. \times 2 ft. 5 in. \times 1 ft. 10 in. out of ground. Rounded. Its longest axis is nearly E. and W. Sandstone, approaching quartzite; not unlike

some of the Yoredale sandstones of the Yorkshire dales. No striations. Rests on fine loamy soil, about 200 ft. above the sea.

On the farm occupied by Mr. Grundon (estate of J. R. Grimston, Esq.), Neswick, S.W. of Driffeld. At present 4 ft. \times 2 ft. 6 in. \times 1 ft. 3 in., but some portion has been broken away. Sub-angular. Not moved by man. Is long-shaped. Longest axis E. and W. Whinstone. 250 ft. above the sea. Isolated. Boulder clay, resting upon chalk.

Grosmont, near Whitby, on the estate of Messrs. Bagnall, Grosmont Iron Works, 2 ft. 3 in. \times 1 ft. 10 in. \times 2 ft. Well rounded. Has been moved. No striæ or groovings. Sharp-fell granite. About 100 ft. above the sea. Was originally found in the bed of the river Esk, which is 300 yards E. of the railway station, and the boulder was found about 50 yards to the N. of the first railway bridge crossing the stream. The boulder rests upon the alum shales of the Lias, through which the river Esk cuts its way.

In Sleights parish, near Whitby; on the Sleights Hall estate, about 300 yards W. of Sleights railway station, and on the E. side of the river Esk, 2 ft. \times 1 ft. 6 in. \times 1 ft. 6 in. out of ground. Sub-angular. Rather long-shaped, but has been moved. No striæ or groovings. Granite. 100 ft. above the sea. Was originally in a small bed of gravel, cut through at the making of the railway. On gravel resting upon the Lias alum shale.

In a grass field three-quarters of a mile due E. from Kirkby Underdale and half a mile S. of Uncleby are two boulders. One is 5 ft. \times 3 ft. 6 in. \times 1 ft. 3 in.; angular; longest axis N. and S. The other is 6 ft. 3 in. \times 3 ft. \times 2 ft. 6 in. above ground; sub-angular; longest axis direct N. and S. These are both composed of ferruginous Oolitic limestone (Inferior Oolite), resting upon the red chalk. No striæ or groovings are visible upon exposed surfaces. Are about 300 ft. above sea-level.

Speeton, near Filey. On Mr. Wilson's farm, in a field, and going from the high road to the house, is a boulder, 2 ft. 9 in. \times 2 ft. 9 in. \times 2 ft. Nearly a square angular block. Whinstone. About 350 ft. above sea-level. Is isolated. Rests on boulder clay.

In a field near the mill belonging to Mr. Plews is a boulder, 3 ft. 7 in. \times 1 ft. 3 in. \times 1 ft. 3 in. Oblong; rounded at each end. No striæ or groovings observed. Whinstone. About 350 ft. above sea-level. Rests on boulder clay, with chalk underlying.

At the corner of Mr. Wilson's garden are three boulders. No. 1—1 ft. 6 in. \times 1 ft. 6 in. \times 1 ft.; angular. No. 2—3 ft. \times 1 ft. 6 in. \times 1 ft.; rounder. No. 3—3 ft. \times 2 ft. \times 2 ft.; sub-angular. No striæ or groovings observed. All are whinstone. About 350 ft. above sea-level. Rests on boulder clay, with chalk underlying.

In the village road leading from the high road are twenty-three boulders, the three largest being of the following dimensions: No. 1—2 ft. \times 1 ft. 2 in. \times 1 ft. 2 in. No. 2—1 ft. 6 in. \times 1 ft. \times 1 ft. No. 3—1 ft. 2 in. \times 1 ft. 2 in. \times 1 ft. Irregularly shaped and angular. The majority are whinstone, the remainder fine sandstone. About 350 ft. above sea-level.

NOTE.—In various parts of the village whinstone boulders may be found, some rounded, others angular. The average size about 1 ft. 3 in. \times 1 ft. Many of them have been moved and are now used for support of stacks and other purposes.

On a farm known as 'Airy Hill,' occupied by Mr. Woodcock, about

one mile E. of Hunmanby and two and a half miles S. of Filey, 2 ft. 4 in. \times 2 ft. 2 in. \times 5 in. A square angular block. Has been moved. No groovings or striæ. A hard sandstone very like Kellaway's rock, 150 ft. above sea-level. Was found on the top of a knoll which is composed principally of boulder clay.

On the same farm are several boulders, in front of the house, which have been collected from adjacent fields. Five are composed of whinstone, varying in size from 2 ft. 10 in. \times 1 ft. 10 in. \times 1 ft. 4 in. to 1 ft. 6 in. \times 1 ft. 6 in. \times 1 ft. There are also three of Shap granite and one of grey granite, the largest being 2 ft. 3 in. \times 2 ft. 2 in. \times 11 in. They are rounded to sub-angular. The surface in this district undulates and any sections are through boulder clay.

On the Glenton farm, on W. side of road leading from Reighton to Filey, are two boulders, 1 ft. 7 in. \times 1 ft. 7 in. \times 1 ft.; grey granite; rounded, 3 ft. \times 2 ft. 10 in. \times 2 ft.; mountain limestone; rounded. No striæ or groovings. Have doubtless been taken from an adjacent ridge of gravel, which runs nearly N. and S.

On Colonel Mitford's estate, and on a farm occupied by Mr. Hornby, a mile and a half E. of Hunmanby and three and a half miles S. of Filey, are two boulders, 1 ft. 3½ in. \times 1 ft. \times 9 in.; 1 ft. 10 in. \times 1 ft. 5 in. \times 7 in. Both are hard, fine-grained sandstone, and have been removed from adjacent land. They originally rested upon the top of a bank close to the cliff. All the above are from 150 ft. to 200 ft. above sea-level.

On the Graffitoe farm, about 100 yards E. of farmstead, two miles E. of Hunmanby, and three miles S. of Filey, are two boulders. No. 1—2 ft. 2 in. \times 1 ft. 11 in. \times 1 ft. 4 in. Sub-angular. Has been moved, but formerly rested upon boulder clay intermixed with gravel. No striæ or groovings. Red sandstone. No. 2—4 ft. 1 in. \times 3 ft. 2 in. \times 2 ft. Oblong and sub-angular. Has been moved, but when found its longest axis was direct N. and S. No striæ. Grey granite. Formerly rested on same bed as preceding boulder.

At the base of a cutting on the North-Eastern Railway, about a mile S. of Filey Railway Station, 3 ft. 6 in. \times 2 ft. 11 in., and projects above the ground about 1 ft. 6 in. Oblong and sub-angular. Has not been moved. Longest axis N. to S. No striæ or groovings. Dark blue whinstone, 150 ft. above sea-level. Is about midway in the centre of a ridge of boulder clay, sand, and gravel.

On the property of Mr. Gullan, Reighton, near Filey, and on the south side of St. Helen's Road (2½ miles from Hunmanby E. and 4½ miles S. from Filey), are two boulders: 2 ft. 2 in. \times 1 ft. 7 in. \times 1 ft. 6 in.; 1 ft. 9 in. \times 1 ft. 6 in. \times 10 in. Both are sub-angular and are dark blue whinstone. They were taken from a ridge of gravel and boulder clay close by, about 150 ft. above sea-level. No striæ or groovings.

On Mr. Crow's Manor farm, about 100 yards W. of Reighton village, are two boulders: 2 ft. 4 in. \times 1 ft. 7 in. \times 1 ft. 2 in.; 1 ft. 10 in. \times 1 ft. 2 in. \times 1 ft. Both are oblong and sub-angular, and are dark blue whinstone. They were both taken from a field close by and were exposed on the surface. No striæ or groovings. Are about the same level as preceding blocks.

At the entrance to Reighton village are four boulders: 3 ft. 5 in. \times 1 ft. 10 in. \times 1 ft.; 2 ft. 3 in. \times 1 ft. 11 in. \times 1 ft. 4 in.; 3 ft. 5 in. \times 1 ft. 1 in. \times 11 in.; 2 ft. 3 in. \times 1 ft. 4 in. \times 9 in. All are oblong and sub-angular, and are dark blue whinstone. Have no striæ or groovings.

Have been in present position beyond memory, but there is little doubt have been originally upon surface of adjoining fields and removed for agriculture, but could not be broken for repairing of roads.

At Cayton, near Scarbro'.—On Dr. Taylor's estate and in the farm-yard of Mr. N. Smith, on the west side of the village; 2 ft. 8 in. \times 1 ft. 9 in. \times 1 ft. 2 in. Angular. Has been moved. No striæ or groovings. Whinstone. It is now used as a mounting block; 150 ft. above sea-level. It rests upon drift composed of gravel, sand, and clay.

On Mr. Hodgson's estate. It is close to Mr. Smith's blacksmith's shop, and used for a seat; also for a mounting stone; 2 ft. \times 1 ft. 8 in. \times 1 ft. 3 in. Sub-angular. Has been moved. No striæ or groovings. Whinstone; 200 feet above sea-level. It rests now upon surface soil.

On Mr. Stead's estate. It now forms the foundation-stone at the south corner of an old house inhabited by W. Fowler, shoemaker, on the side of the village main street; 1 ft. 9 in. \times 1 ft. 6 in. \times 1 ft. 3 in. Flat angular block. Has been moved. No striæ or groovings; 150 ft. above sea-level. Whinstone.

Is about 100 yards E. of the railway station; at the N. side of the road, close to the gate, leading into the valley field occupied by Mr. N. Smith; 2 ft. 2 in. \times 1 ft. 8 in. \times 1 ft. Sub-angular. Probably has been moved. No striæ or groovings. Whinstone; 150 ft. above sea-level. Rests on surface soil.

In the foundations of an old cottage, belonging to Mr. Stephenson, on the E. side of the street. This cottage is about 250 yards N. of the church; 2 ft. 7 in. \times 1 ft. \times 1 ft. 2 in. Rounded and oblong. Has been moved. No striæ or groovings exposed. Coarsely grained dolerite; 150 ft. above sea-level. Rests on surface soil.

On Mrs. Wilson's estate; in the centre of the village on the W. side of the Scarbro' and Filey road; 2 ft. 5 in. \times 1 ft. 10 in. \times 1 ft. 3 in. Rounded. Has been moved. No striæ or groovings. Dolerite. 200 ft. above sea-level.

NOTE.—The possession of this boulder is at present in dispute. It originally was in the foundation of some very old thatched cottages, and when the new property was built some years ago a large block of sandstone was given in exchange, and now that the sandstone is a fixture they dispute the other being taken away.

On Dr. Layton's estate, Cayton Carr, about a mile and a half W. of Cayton village. It was taken out of a ridge of gravel that runs through the centre of a field, called the Six Acre Strip, in the occupation of Mr. Smith. Its present position is close to the gate entering the field in which it was found; 2 ft. 4 in. \times 1 ft. 7 in. \times 9 in. Sub-angular. No striæ or groovings. Whinstone; 250 ft. above sea-level.

NOTE.—In a heap close by are several smaller boulders taken out of the same field, comprising grey granite, red granite, mountain limestone, whinstone, and sandstone.

Is at the S. corner of a wall surrounding the engine-house of the Scarbro' Waterworks Company, about one mile E. of the village of Cayton; 2 ft. \times 1 ft. 8 in. \times 1 ft. 3 in. Rounded. Long-shaped. No striæ or groovings. Mountain limestone.

NOTE.—It was brought from the beach below to strengthen the corner of the wall.

In a by-road leading from Cayton to Scarbro' is a large number of

boulders of which upward) of thirty will average 1 ft. 4 in. \times 9 in. and over seventy others are over a foot in diameter. The larger ones are sub-angular; the smaller ones rounded. All have no doubt been conveyed from adjacent fields. No striæ or groovings are to be seen on exposed surfaces. They are different kinds of sandstone. They are about 150 ft. above sea-level.

On Miss Craven's estate, in the village of Cayton, about 300 yards N. of the church, and on the main road to Scarbro', is a group of nine boulders, four of which are whinstone, and upon an average 1 ft. 11 in. \times 1 ft.; the other five are sandstone and average 1 ft. 8 in. \times 1 ft. 2 in. The whinstones are mostly sub-angular; the sandstones angular. There are no striæ or groovings exposed. They are about 150 ft. above sea-level. Some of them are entirely exposed, the rest being partially covered with other stones and soil.

On Miss Craven's estate in the village of Cayton, and about 250 yards N. of the church, in a by-road called North Lane, are a number of boulders, the seven largest of which I have noted as follows:—No. 1—1 ft. 11 in. \times 1 ft. 4 in. \times 1 ft.; red sandstone; angular. No. 2—2 ft. 6 in. \times 1 ft. 2 in. \times 1 ft.; whinstone; angular. No. 3—1 ft. 10 in. \times 1 ft. 4 in. \times 1 ft. 3 in.; whinstone; rounded. No. 4—1 ft. 5 in. \times 1 ft. 3 in. \times 1 ft.; hard, grey sandstone; sub-angular. No. 5—1 ft. 6 in. \times 1 ft. \times 9 in.; whinstone; rounded. No. 6—1 ft. 4 in. \times 9 in. \times 7 in.; mottled granite; sub-angular. No. 7—2 ft. 4 in. \times 1 ft. 2 in. \times 6 in.; whinstone; angular. I could not observe any striæ or groovings. The rising ground is principally composed of drift, gravel, sand, and clay, whilst the hollows are filled with deep peat bogs.

NOTE.—The great bulk of the boulders in this district are composed of sandstone and whinstone; of these thousands have been broken up and used to mend the roads from time unknown. There is no doubt about the roads having received their supply of metal from this source. Those left behind (as above) are those which could not be broken up, or which have been taken out of the land at a recent date.

Lebberston, near Scarbro'.—On Mr. Wardell's estate, in a grass-field at the E. end of the village, and about 100 yards W. of the Scarbro' and Filey road, 4 ft. 3 in. \times 2 ft. 5 in. \times 2 ft. 7 in., but evidently one-half of it is embedded; sub-angular. Longest axis N.W. to S.E.; should think it has not been moved. There are remains of several groovings, which are much worn, and there are also striæ on the side of the block, in the direction of the longest axis. Whinstone. Is 200 feet above sea-level. Is near the top of a ridge of gravel drift.

On Mr. Jackson's estate, at the E. end of the village, near a yard door on the W. side of the road, 2 ft. 3 in. \times 1 ft. 9 in. \times 2 ft. 3 in. Angular, and is used as a stepping or mounting stone. Has been moved, but is known to have been in its present position for more than a century. No striæ or groovings. Whinstone. 200 ft. above sea-level. No doubt has been obtained from gravel drift in vicinity, but now rests on the surface soil.

On Mr. H. Watson's estate. Is in a grass-field, about a quarter mile N. of the Gristhorpe Railway Station, Hull and Scarbro' branch, 4 ft. 2½ in. \times 2 ft. 5 in. \times 3 ft. 6 in., and partially embedded. Sub-angular, flat on one surface. Long-shaped; its bearing N. and S. There appear to be some striæ, which have become very faint from exposure, but the stone being grown over with lichen, they are difficult to determine.

Upon the under side, however, is a well-defined groove about 1 ft. long. Whinstone. The popular tradition is, that it was thrown by his Satanic Majesty at one of his satellites for staying out too long. An old farmer avers he found it one morning, but the previous evening it was not there. 200 ft. above sea-level. Rests on boulder clay.

On Mr. Welburn's estate, and upon a farm in the village occupied by Mr. R. Brown, are two boulders, 150 ft. above sea-level. Dimensions of No. 1 boulder: 3 ft. 2 in. \times 1 ft. 10 in. \times 1 ft. 2 in. Sub-angular. Has been moved. Whinstone. Dimensions of No. 2 boulder: 3 ft. 2 in. \times 2 ft. \times 1 ft. 8 in. Angular. Has been moved. Whinstone. Both have evidently been found in the land. No. 2 was dug out of the garden in front of the house close to the street, and moved to its present position. Lebberston village is situated on a ridge of gravel.

In Leys Lane, at the entrance to the village of Lebberston, on the N. side of the lane and W. end of village, is a group of boulders. No. 1—2 ft. 7 in. \times 1 ft. 6 in. \times 9 in., and No. 2—2 ft. 3 in. \times 1 ft. 3 in. \times 10 in.; whinstone; sub-angular. No. 3—2 ft. 1 in. \times 2 ft. 1 in. \times 1 ft. 2 in.; coarsely grained dolerite; rounded. No. 4—2 ft. 4 in. \times 1 ft. \times 9 in., and No. 5—2 ft. 1 in. \times 1 ft. 6 in. \times 1 ft.; sandstone; sub-angular. There are no striæ or groovings upon them. They are about 100 ft. above sea-level; are all close together and exposed on the surface.

There is a boulder in the North-Eastern Railway cutting, about one mile N. of Filey, in the direction of Gristhorpe, 2 ft. 10 in. \times 2 ft. 3 in. \times 1 ft. 4 in. Rounded; pear-shaped. Has been moved; is now at the base of the cutting laid across a gutter or waterway. No striæ or groovings. Dark blue whinstone. 200 ft. above sea-level. Was connected with a long ridge of gravel, sand, and clay, which was cut through when making the line.

There is a boulder in the North-Eastern Railway cutting about 200 yards N. of Gristhorpe Station, and on the east bank of the cutting. It is in the parish of Gristhorpe, near Scarbro', 2 ft. \times 1 ft. 10 in. \times 1 ft. Angular, almost square; longest axis N. and S. Has not been moved. No groovings or striæ can be seen, but it is now almost covered with soil which has fallen from above. It is a light-coloured sandstone, like the moor grit near Scarbro'; 200 ft. above sea-level. It is in a bank of rough gravel, clay, and sand.

In the parish of Seamer, near Scarbro' (N. Riding), about three miles S.S.W. of Scarbro' and about two miles S.E. of Seamer village, and close to Seamer Junction, North-Eastern Railway, on the estate of Lord Londesborough, is a group of boulders. No. 1—1 ft. \times 9 in. \times 6 in.; red granite. No. 2—2 ft. 6 in. \times 1 ft. 10 in. \times 1 ft. 4 in.; Shap granite. No. 3—1 ft. \times 1 ft. \times 9 in.; Shap granite. No. 4—1 ft. 6 in. \times 1 ft. \times 9 in.; Shap granite. No. 5—1 ft. 2 in. \times 1 ft. \times 8 in.; Shap granite. No. 6—1 ft. 8 in. \times 1 ft. 6 in. \times 9 in.; Shap granite. No. 7—1 ft. 6 in. \times 1 ft. 2 in. \times 8 in.; mica schist. No. 8—1 ft. 6 in. \times 1 ft. 6 in. \times 1 ft. 6 in.; red granite. All are rounded. They have been moved, but were obtained from the Seamer gravel drift. No striæ or groovings are visible. About 200 ft. The gravel drift of Seamer overlies the Coralline Oolite.

The Committee have been favoured by the Rev. A. W. ROWE, of Felstead, with the following Report upon boulders in N.W. Essex.

The boulders mentioned in the accompanying list are all lying within the limits of a small district in the N.W. of Essex: a few only have been

specified which are less than 12 inches in length, though there are an immense number which fall only a little short of that limit, especially boulders of igneous rocks: but even with the omission of these the list is not by any means an exhaustive one, as some portions of the district have scarcely been examined. They have been found within six miles of the village of Felstead, which will be found marked on the Ordnance Map nearly mid-way between Braintree on the east, Dunmow on the west, Little Saling on the north, and Great Waltham on the south. The general character of the district is that of a tableland, ranging from 200 to 250 feet above sea-level, intersected by small valleys cut out chiefly by local streams. The superficial deposits are chalky boulder clay and beds of glacial gravel: these gravel beds really underlie the chalky boulder clay, as could be well seen in the railway cutting $\frac{3}{4}$ mile west of Dunmow Station before it was overgrown, but owing to the extensive denudation of the clay the beds of gravel are frequently found at the surface on the high ground. London clay underlies all these superficial deposits, and in several valleys, notably that of the Chelmer, the streams have cut their way down to it; nearly all the larger boulders have been found on the high ground. Some of these seem to require special mention. Of the sandstone boulders three measure respectively $77 \times 36 \times 20$ in. and $64 \times 63 \times 14$ in. and $61 \times 34 \times 17$ in., this last having a circumference of 158 inches, and nine others exceed 40 inches in length, including the conglomerates: nearly all appear to be unfossiliferous, but in one, which in texture and general appearance may be considered characteristic of the greater number, I found some small fragments of Crinoid stems and some casts of portions of *Aviculopecten*: in another rounded boulder of about 12 in. in diameter I found some very well defined casts of *Productus* (*P. semireticulatus*, *P. Martini*, *P. orthoceras*, *P. hemisphericus*), *Streptorhynchus crenistria*, *Euomphalus pentangulatus*, *Bellerophon*, showing that the boulder was millstone grit; and Mr. H. Keeping, who also examined the casts, tells me that it agrees very well with the beds of buff sandstone near Oswestry. In two other large boulders, which I have described in a previous paper ('Q. J. G. S.' August 1887, p. 360) as being masses of a greyish yellow sandstone permeated with a thin film of calcite, giving them a peculiar glazed appearance wherever fractured, I found fragments of *Pecten orbicularis*. Mr. Whitaker informed me that a great number of boulders of this rock are found in the boulder clay in Norfolk, and Mr. Keeping identified it as being of the same character as that which occurs in the Spilsby beds in Lincolnshire. Another very large boulder of a buff coloured sandstone, fine-grained but not very compact, was dug out of the bottom of a pond a few weeks ago: it contains *Belemnites* in abundance, some of a large size. Among numerous boulders of Hertfordshire pudding-stone there are two which measure respectively $52 \times 23 \times 16$ in. and 52×43 in., this latter being so completely buried in the ground that its thickness could not be ascertained. The limestone boulders are fragments of Carboniferous, Jurassic, and Cretaceous rocks. The Carboniferous are almost without exception so exceedingly fine that scarcely any fossil shells can be detected in them without the aid of the microscope, the one exception being a boulder lately dug up at Bocking Place almost entirely composed of shells of *Productus giganteus*. Of the Jurassic rocks two boulders of Kimmeridge clay, taken out of the chalky boulder clay in the cutting near Dunmow, were wonderfully

striated with deep grooves of almost parallel striæ on two sides, and many of the boulders of clunch and hard chalk are also clearly striated, but the direction of the striæ is very irregular. Among the whitened flints also there are some exceedingly good examples of cross-striation. Striæ are not often to be seen on the hard sandstones and the igneous boulders, though there are a few good examples of it; but most of these boulders are quite smoothed and some are highly polished. Of the igneous rocks some are so much weathered that the outer surface comes off in successive coats, like a thick-coated onion, whereas others, and especially the larger boulders, are perfectly unweathered and have a very dark almost black polished surface, so hard and rounded that it is often exceedingly difficult to get a hand specimen. They consist mainly of fine-grained dolerites and microcrystalline basalts, with a fair sprinkling of quartz-porphyrates, mostly containing tourmaline, felspar-porphyrates, and hornblende schists and gneiss. Amid the almost complete absence of boulders, or even pebbles, of granite or syenite, one boulder which I have lately found is remarkable: it is a large boulder of a pinkish grey syenite, of very distinct rather coarse texture and containing abundant orthoclase, not much quartz, not a great amount of hornblende, and a little biotite. Dr. A. Geikie has seen a hand specimen and microscopic section of it, and he informs me that he cannot identify it with any British rock known to him, and that Dr. Hatch cannot find any specimen at the Jermyn Street Museum really like it. I have also been informed by Dr. Crosskey that nothing like it has been found among the erratics in the Midlands, though a considerable number of boulders of syenite have been found there. I have sent a hand specimen to Christiania to see if it can be identified there. In a gravel pit on the high ground near Felstead I dug out a remarkable boulder of quartz and tourmaline, almost round and highly polished and striped with parallel bands of black and yellow, and among the specimens of erratics in the Midlands which Dr. Crosskey has collected I found one that was identical with it. Of the boulders of dolerite it is somewhat remarkable that, although smaller boulders occur in all directions, yet all the larger boulders which I have at present found lie north of the old Roman road which runs through Braintree and Dunmow; as many as six large boulders are lying within a comparatively small area, one of these being distinctly columnar in form and one being very clearly striated. As regards the dolerites generally I have already stated ('Q. J. G. S.' August 1887, p. 356) that some of them are strikingly similar in specific gravity, in general appearance, and in some remarkable microscopic points with some specimens of dolerites sent me from Sweden, and that others are almost identical with the rocks of the Whin Sill in the north of England, though these also might well be Scandinavian boulders, as I understand that the Hunneberg rocks have been shown to be of the Whin Sill type. But one of the most remarkable of the boulders which I have as yet found was exposed in digging the foundations of a new house at Bocking Place, Braintree (Mr. S. Courtauld): it was found at a depth of eight feet from the surface and measures $22 \times 18 \times 11$ in.; it is rounded and smoothed, roughly triangular in shape, and has two more or less flat surfaces: both of these surfaces are very distinctly grooved with irregular striæ. I sent a hand specimen and a microscopic section to Professor Bonney, who kindly examined both and wrote as follows: 'The rock is a curious one and must have come a long distance. . . . So far as I can venture to

pronounce, the aspect of the slide reminds me rather of a modified crystalline rock than a partially crystallised sedimentary rock. It is therefore now a kind of gneiss—what I should call a pressure-gneiss—resulting from the modification of a crystalline rock which may have been a quartziferous mica-diorite. The fragmental aspect I attribute to the result of pressure which has acted on a crystalline rock, and has been followed by a certain amount of mineral change in the constituents; of course an *arkose* of the right constituents might give a similar appearance, but though the enlargement of fragments *in situ* is not unknown, it is not common and generally occurs (except in the case of quartz) in very ancient rocks only. The boulder must have had a long journey, for such a rock could not be found *in situ* nearer than the Scotch Highlands or Scandinavia.'

BOULDERS IN ESSEX, N.W.

District on the Ordnance Map, Little Saling, N. ; Great Waltham, S. ; Braintree, E. ; Dunmow, W. ; centre of district, Felstead ; radius, from five to six miles.

Parish, *Great Saling*, 4 miles N.E.

1. In Village Street—Boulder of dolerite, $33 \times 29 \times 18$ in. ; roughly conical in shape ; rounded and polished ; no striæ visible ; olivine-dolerite.
2. In Newbister Lane—Three smaller boulders of dolerite, less than 12 in. in diameter ; one olivine dolerite, the others plagioclase-augite rock.

Parish, *Little Saling*, 5 miles N.N.E.

1. By the church wall—Boulder of calcareous sandstone, $61 \times 34 \times 17$ in. ; circumference, 158 in. ; pudding-shaped ; rather soft loose texture ; dark grey colour ; fine-grained, with fragments of shells.
2. At farm near the church—Boulder of sandstone, $45 \times 35 \times 24$ in. ; oblong ; slightly striated ; rather soft ; fine-grained ; buff-coloured ; containing many Belemnites ; quite lately dug out of the bottom of a pond ; Kellaways rock (?). Boulder of dolerite, $37 \times 30 \times 18$ in. ; roughly triangular ; distinctly striated on two surfaces with parallel striæ ; rest polished ; olivine-dolerite.
3. At Woolpits Farm—Boulder of dolerite, $39 \times 38 \times 19$ in. ; nearly square ; distinctly striated and polished ; dug out of a ditch on the farm ; plagioclase and augite ; no olivine.

Parish, *Stebbing*, 3 miles N.

1. At Mount Farm—Boulder of sandstone, $64 \times 63 \times 14$ in. ; flat, sub-angular ; fine-grained ; white colour ; lately dug up on the farm. Boulder of sandstone, $22 \times 20 \times 12$ in. ; sub-angular ; fossiliferous. Boulder of sandstone, $23 \times 19 \times 9$ in. ; rounded ; gritty ; grey colour ; unfossiliferous. Boulder of dolerite, $30 \times 26 \times 17$ in. ; columnar dolerite ; shape well marked ; microcrystalline ; no striæ, but highly polished.
2. Stebbing Green—Boulder of dolerite, $30 \times 27 \times 24$ in. ; conical shape, with semicircular base ; no striæ, but highly polished.
3. In fields near the Green—Five smaller boulders of dolerite under 12 in. in diameter, one being a highly vitreous olivine-basalt.
4. At Green Farm—Boulder of quartz rock, $20 \times 16 \times 11$ in. ; rounded ; polished ; yellow colour. Boulder of quartzite, $16 \times 12 \times 11$ in. Boulder of felsite, $12 \times 10 \times 9$ in. ; oblong ; dark grey ; very compact and hard.

Boulder of dolerite, $29 \times 24 \times 11$ in.; oblong; rounded; very much weathered.

5. At Scallops Farm—Boulder of limestone, $29 \times 24 \times 8$ in.; sub-angular; Carboniferous limestone. Boulder of sandstone, $22 \times 21 \times 10$ in.; sub-angular; compact; bright red colour. Boulder of porphyrite, $12 \times 11 \times 8$ in.; rounded; quartz-porphyrity (?).

Parish, *Little Easton*, 6 miles N.W.

1. Near the Park Gates—Boulder of sandstone, $42 \times 40 \times 21$ in.; rounded; oblong; fine-grained; compact; pinkish yellow. Boulder of sandstone, $36 \times 30 \times 20$ in.; oblong; fine-grained; compact, greyish yellow; very clearly striated, and in parts highly polished. Boulder of sandstone, $27 \times 24 \times 20$ in.; very similar to last mentioned, but not striated. Boulder of sandstone, $24 \times 24 \times 13$ in.; very similar to last two. Boulder of limestone, $28 \times 24 \times 10$ in.; rounded oblong; exceedingly fossiliferous; Oxford clay (?). Two boulders of conglomerate (pudding-stone), $34 \times 20 \times 14$ in. and $30 \times 24 \times 13$ in.

Parish, *Little Dunmow*, 2 miles N.W.

1. At Blatches Farm—Boulder of sandstone, $48 \times 41 \times 13$ in.; oblong; fine-grained; sub-angular; traces of striæ on upper surface. Small boulder of olivine-basalt.

2. At Bouchiers Farm—Boulder of flint, $19 \times 14 \times 6$ in. Boulder of syenite, $22 \times 15 \times 9$ in.; oblong, rounded; rather coarse-grained; greyish yellow. Two boulders of limestone (Carboniferous), $27 \times 22 \times 6$ in. and $30 \times 22 \times 11$ in.; pinkish colour; fine-grained, much cracked. Boulder of calcareous grit, $21 \times 18 \times 11$ in.; very coarse, and rather loose texture. Two boulders of sandstone, $46 \times 22 \times 17$ in. and $36 \times 30 \times 19$ in.; fine-grained; compact; whitish yellow; rounded and polished. Boulder of dolerite, $18 \times 12 \times 6$ in.; oblong; much weathered; crust peeling off in coats. Small boulder of olivine basalt; rounded and very much weathered.

At Parsonage Farm—Boulder of sandstone, $48 \times 42 \times 19$ in.; oblong; rounded; slightly striated; micaceous. Boulder of limestone (Carboniferous), $23 \times 14 \times 12$ in.; oblong; smoothed; clearly striated in direction of longer axis. Boulder of sandstone, $18 \times 15 \times 5$ in.; rounded; exceedingly compact.

In Cap Lane—Large pebble of grey syenite.

Road near village—Boulder of felsite; spherulitic.

At Burnt Cottage—Two boulders of clunch (Oxford clay?), $13 \times 8 \times 5$ in. and $12 \times 8 \times 7$ in.; just dug out of chalky clay; very clearly striated. Several large whitened flints, also striated. In gravel pit—Boulder of quartz-tourmaline rock; rounded and highly polished; curiously striped.

Parish, *Barnston*, 2 miles W.

At Absol Park Farm—Boulder of limestone (Carboniferous); oblong; rounded and smoothed; finely crystalline.

Near Rectory—Small boulder of mica schist; very small boulder of syenite.

Parish, *Great Waltham, North End*, $1\frac{1}{2}$ mile S.S.W.

At North End Place—Boulder of sandstone, $35 \times 19 \times 18$ in.; sub-

angular; no striæ; very fine-grained; white. Boulder of sandstone, $25 \times 16 \times 14$ in.; sub-angular; no striæ; fine-grained; yellow. Two boulders of conglomerate (pudding-stone), $21 \times 18 \times 11$ in. and $16 \times 11 \times 6$ in.; one very coarse and pebbles varying in size, the other with much smaller pebbles and all of a size.

In lane—Large boulder of felspar porphyrite; rounded and polished, and very hard.

Parish, *Great Waltham, Ford or Fourth End*, 3 miles S.

Ford End Hill—Boulder of sandstone, 19×10 in.; buried in ground; grey; micaceous. Boulder of limestone (Carboniferous), 16×16 in. Boulder of flint, 19×14 in. Boulder of sandstone, 16×11 in.; gritty, red.

At Hill Farm—Boulder of sandstone; $30 \times 19 \times 11$ in.; ridge-shaped; sub-angular; fine-grained; yellow. Boulder of sandstone, $29 \times 22 \times 20$ in.; oblong; rounded; gritty and loose; white. Four boulders of sandstone, respectively $28 \times 24 \times 16$ in.; compact; yellow, $21 \times 17 \times 16$ in.; conical; compact; yellow, $17 \times 16 \times 12$ in.; sub-angular; hard; greyish yellow, $16 \times 13 \times 7$ in.; sub-angular; gritty; micaceous. Two smaller boulders of dolerite.

At Littley Park, 2 miles S.S.E.—Boulder of sandstone, $33 \times 25 \times 22$ in.; roughly columnar; much polished; compact; yellow.

At Littley Green, $2\frac{1}{2}$ miles, S.S.E.—Boulder of limestone (Carboniferous), $28 \times 26 \times 12$ in.; nearly square; striated; hard; compact; fine-grained.

Parish, *Little Leighs*, 4 miles S.E.

Near Leighs Priory—Boulder of dolerite, $13 \times 9 \times 6$ in.; much weathered. Smaller boulder of dolerite. Large boulder of felspar porphyry broken in several pieces; matrix bright red; felspar very clear. Sandstone, $26 \times 16 \times 7$ in.; much polished; compact; yellow.

Parish, *Great Leighs*, 6 miles S.E.

At Fulbourn's Farm—Boulder of conglomerate, buried in ground so that surface is level with ground, 52×43 in.; Herts. pudding-stone. Boulder of sandstone, $48 \times 20 \times 12$ in.; ridge-shaped; compact; yellow.

Parish, *Braintree*, 6 miles E.N.E.

At Bocking Place—Boulder of gneiss, $22 \times 18 \times 11$ in.; roughly triangular, with two flat surfaces, deeply striated irregularly. Boulder of limestone (Carboniferous) almost composed of large shells of *Productus*.

Parish, *Felstead*.

At Princes Halfyards Farm, $1\frac{1}{4}$ mile N.—Boulder of sandstone, $77 \times 36 \times 20$ in., fixed deeply in ground, so that 36 in. does not represent its real height; gritty, yellowish, grey. Three boulders of dolerite, broken up before being measured, but none exceeding 12 in. in diameter.

At Moor Farm, $1\frac{1}{2}$ mile N.E.—Boulder of dolerite and boulder of porphyrite, both broken up, not exceeding 12 in. in diameter.

At Cock Green, 2 miles S.E.—Boulder of dolerite, almost circular, scarcely weathered, rather over 12 in. in diameter; hypersthene-bearing ophitic dolerite.

At French's Green, 3 miles E.—Very large boulder of compact yellow sandstone, since removed. A large heap of several hundred

smaller boulders lately dug up in land-ditching, chiefly flints, but containing also porphyrite, olivine-basalt, dolerite, Mountain limestone, Jurassic limestone, and ferruginous sandstone.

At Whelpstones Farm, $2\frac{1}{2}$ miles E.S.E.—Large boulder of compact yellow sandstone split into two halves, one half being left in the ground, the half removed to farmyard measuring $27 \times 21 \times 16$ in. Boulder of sandstone, $20 \times 16 \times 10$ in., soft, buff-coloured.

At Pond Park, $1\frac{1}{2}$ mile S.E.—Boulder of sandstone, $40 \times 39 \times 17$ in.; oblong, much smoothed, glazed with calcite, Lower Cretaceous. Two boulders of septaria with veins of calcite, $25 \times 21 \times 8$ in. and $22 \times 16 \times 12$ in. Two boulders of flint, $20 \times 13 \times 8$ in. and $20 \times 9 \times 11$ in., whitened, not striated. Boulder of sandstone just dug up, $32 \times 22 \times 11$ in., subangular, polished, whitish yellow, compact. Five boulders of sandstone, $24 \times 12 \times 11$ in. compact, light yellow; $18 \times 15 \times 7$ in., compact, deep red; $17 \times 8 \times 6$ in., compact, grey; $14 \times 6 \times 7$ in., compact, light yellow; $13 \times 11 \times 6$ in., compact, yellowish white. Boulder of conglomerate (pudding-stone), $19 \times 14 \times 6$ in. Several smaller boulders of dolerite.

At Potash Farm, 1 mile S.S.E.—Boulder of sandstone, $40 \times 33 \times 16$ in., much polished, but not striated; compact, yellow. Boulder of sandstone dug up in May and brought to farmyard, $31 \times 30 \times 15$ in., oblong, yellow, not very compact. Boulder of sandstone, $17 \times 15 \times 8$ in., rather coarse and gritty, red. Five smaller boulders, all measuring 12 in. or over. Two boulders of quartz rock, $14 \times 8 \times 7$ in. and $14 \times 13 \times 7$ in.

At Causeway End, $\frac{3}{4}$ mile S.—Four boulders of sandstone, all exceeding 12 in. and polished. Large boulder of dolerite dug out in clay pit from boulder clay, and found to be split into several large fragments; olivine dolerite, containing unusual quantity of magnetite.

In Snows Lane, 1 mile S.W.—Two boulders of olivine dolerite not exceeding 12 in.

At Mill House, 1 mile S.W.—Boulder of sandstone, striated and polished.

At Bury Farm, in the village—Boulder of conglomerate (pudding-stone), $52 \times 23 \times 16$ in. Boulder of contorted gneiss, $15 \times 15 \times 14$ in., rounded and much polished, hornblende gneiss. Seven boulders of sandstone, $35 \times 20 \times 11$ in., compact, yellow; $30 \times 21 \times 6$ in., very compact, yellow; $19 \times 18 \times 12$ in.; $18 \times 9 \times 8$ in., gritty, yellow; $17 \times 14 \times 11$ in., fine, compact, yellow; $16 \times 15 \times 6$ in., compact, grey; $14 \times 11 \times 5$ in., gritty, yellow. Two boulders of flint, $20 \times 11 \times 8$ in. and $18 \times 13 \times 3$ in. Boulder of quartzite, $15 \times 15 \times 5$ in. Boulder of quartz rock $14 \times 11 \times 6$ in., rounded and polished. Four boulders of limestone (Carboniferous), $23 \times 12 \times 7$ in. and $19 \times 9 \times 7$ in.; $20 \times 17 \times 5$ in. and $15 \times 10 \times 9$ in., much smoothed and rounded, of fine texture and grey colour. Three boulders of mica-schist, one being garnetiferous, the garnets being decomposed. Two boulders of quartz porphyrite, one containing schorl. One large fragment of silicified wood, coniferous (?). Two boulders of dolerite, very much weathered.

At Chequers Inn—Boulder of limestone (Carboniferous), $26 \times 18 \times 12$ in., much rounded and smoothed. Boulder of calcareous sandstone, $30 \times 24 \times 18$ in.

At Vicarage—Boulder of sandstone dug up in the churchyard, $32 \times 16 \times 15$ in., oblong, yellow, gritty.

At Sewell's Farm—Boulder of millstone grit not exceeding 12 in., containing abundant casts of shells, soft, buff-coloured.

At Felstead Place—Boulder of dolerite, broken up before it could be

measured. Boulder of sandstone, $37 \times 17 \times 12$ in., oblong, much smoothed, compact.

At Coal Yard—Boulder of sandstone, $34 \times 20 \times 15$ in., oblong, rounded and smoothed, compact, greyish yellow.

In Village Street—Fourteen boulders of sandstone, smoothed and rounded, $21 \times 16 \times 6$ in., fine-grained, compact, yellow; $24 \times 18 \times 6$ in., fine-grained, compact, yellow; $18 \times 10 \times 11$ in., gritty, loose, very dark, almost black; 26×10 in. (buried), 23×9 in. (buried), and 18×7 in. (buried), very compact, mottled, bright red and yellow, fine, compact; $31 \times 11 \times 11$ in., fine, compact, yellow; $17 \times 11 \times 11$ in.; $14 \times 13 \times 10$ in., grey brown, gritty, glazed with calcite; $17 \times 12 \times 9$ in., very compact, reddish yellow; $20 \times 10 \times 9$ in., fine, compact, grey; $22 \times 17 \times 13$ in., fine, grey; $17 \times 11 \times 10$ in. and $22 \times 19 \times 6$ in., coarse, gritty, glazed with calcite. Two boulders of flint, $27 \times 10 \times 6$ in. and $23 \times 11 \times 5$ in. Three boulders of dolerite, $15 \times 9 \times 8$ in. and $12 \times 9 \times 10$ in., and one under 12 in.

LANCASHIRE AND CHESHIRE.

A valuable list and description of erratics which have been found in the drainage areas of the Oldham Corporation Waterworks by Mr. W. Watts will be found in the 'Transactions of the Manchester Geological Society,' Session 1887-88, p. 584 *et seq.*

In the 'Transactions' of the same society (Feb. 7, 1888) Mr. Herbert Bolton describes the boulders in the high level drift of Bacup.

Mr. Ratcliffe furnishes the following description of the erratics in Dukinfield, Stalybridge, Millbottom, and Micklehurst. The term 'boulder clay' is used to denote the clays, marls, sands, and gravels containing boulders, but must not be taken as always synonymous with the lower boulder clay or 'till.'

At Dukinfield the boulder clay rests upon the edges of the Upper, Middle, and Lower Coal measures, from the river Tame to Line Edge, and beyond to the base of Harrop Edge the drift consists of alternate layers of clay, sand, and gravel; in some cases thick layers of marl come in between the upper sand and gravel.

The top clay is extensively used for brick-making, the sand for building and moulding purposes. The gravel contains often large boulders, and almost in every case yields large quantities of water.

At Dukinfield Hall there is a total depth of 20 ft. 7 in. to the rock head, whilst to the north at Ashton Moss Colliery the section in the sands, clays, and gravels, of which the boulders are formed, is as follows:—

	ft.	in.
Soil turf and sand	4	0
Strong marl	11	0
Sand and marl	1	6
Dark wet sand	8	2
Strong marl	11	4
Sand and gravel	2	0
Dry sand	8	6
„ gravel	0	6
„ sand	26	4
„ marl	6	0
„ sand	11	6
Wet „	17	6
Strong marl	26	8
Marl and stones mixed	7	11
	<hr/>	
	142	11

To the east of the Ashton Moss Colliery the Lords' Field Colliery passed through the following:—

	ft.	in.
Soil and clay	6	0
Strong marl	43	6
Dry sand	24	0
Wet „	4	0
Strong brown marl	101	9
Wet gravel, 7,000 gallons of water per hour	7	9
		<hr/>
To rock head	187	0

Returning to the Cheshire side of the river Tame the drift covers the edges of the middle series, the dip of which is west at an angle varying from 18° to 42°, and along the line of Chapel Hill, where it covers the lower seams of the middle series. The following is a section at Victoria Colliery:—

	ft.	in.
Soil	0	6
Clay	2	0
Marl	9	6
		<hr/>
To rock head	12	0

The boulders distributed over this area, extending from the river Tame at Dukinfield Hall to Lyne Edge, varying in size from a few hundredweight to three tons, are found mostly resting upon the marl at the base of the gravel beds, and consist of felsites, hornblendic granites, andesite, and andesitic ash, some micro-granites and Eskdale granites. They are mostly rounded, sub-angular, and in some cases striated.

Beyond Lyne Edge to the base of Harrop Edge, where the millstone grit appears, are strong marls, with sand and gravel beds beneath. In the marl a few feet below the soil are boulders, smooth and well rounded, consisting of andesitic ash, rhyolitic breccia, Eskdale granite, vein rock, and crushed altered ash.

Along the base of Shaw Moor the boulder clay is upwards of 30 ft. thick, containing a variety of small boulders, pieces of gannister, &c. One large boulder, a felsite from the Lake district, is upwards of seven tons in weight; another is rather smaller in size, a felsite with epidote, also from the Lake district; another is about thirty hundred-weight, and is a Criffel granite from the S.W. of Scotland.

The boulder clay from the river Tame to the base of the hills, from Millbottom to Micklehurst, consists of boulder clay resting upon sand, and gravel, from which a good supply of water can be readily obtained.

The clay contains a large number of small boulders, often intermixed with thin bands of sand and small gravel, and occasionally larger boulders of the Eskdale series: andesitic ash (crushed), felsites, syenite, vein rock, and hornblendic granite from Buttermere. These are rounded, smooth, the softer portions showing slight striations.

The following sections show the exact positions of some of the erratics at different points in the area described:—

	ft.	in.
Soil	0	6
Sand	5	0
BOULDERS—		
Loam and sand	7	6
Gravel	2	0
Sand with water	6	0
		<hr/>
Rock base	21	0

										ft.	in.

										ft.	in.
Soil and gravel	12	0
BOULDERS—											
Marls	8	7
Rock base	20	7

Mr. Plant continues his reports and describes the erratic blocks at Spinney Hills, near Leicester.

A fine group of blocks has been uncovered on the Spinney Hills, to the east of Leicester; they were scattered over about two acres of land, and lying on the lower Rhætic beds, under about 6 ft. of a stiff upper boulder clay which covers these hills, and varies from 3 to 12 ft. deep, and is succeeded by the hard white clay and shales of the Rhætic beds. All the blocks except two are granite from Mount Sorrel, $6\frac{1}{2}$ miles distant due N. The following is a list:—

					Length.	Breadth.	Depth.
No. 1	3 ft. 3 in.	× 3 ft. 0 in.	× 2 ft. 6 in.
No. 2	3 ft. 0 in.	× 2 ft. 10 in.	× 2 ft. 0 in.

No. 2 block is unique, being the first I have found that has a *smooth polished surface* and slightly striated, the edges and angles clean and sharp. The above will be removed to the Museum grounds at Leicester. The other blocks are as follows:—

					Length.	Breadth.	Depth.
No. 3	2 ft. 0 in.	× 2 ft. 0 in.	× 1 ft. 6 in.
No. 4	2 ft. 0 in.	× 1 ft. 8 in.	× 1 ft. 0 in.
No. 5	2 ft. 6 in.	× 1 ft. 6 in.	× 1 ft. 0 in.
No. 6	1 ft. 6 in.	× 1 ft. 6 in.	× 1 ft. 0 in.

The above blocks are roughly cubical, the angles and edges are sharp and some of the sides quite fresh, *i.e.*, not weather-worn. Besides these, seven other smaller blocks, rough cubes, of 1 ft. 6 in. on the face; these are of Mount Sorrel granite, $6\frac{1}{2}$ miles distant; two others about the same size, but much rounded and worn, were coarse sandstones or millstone-grit, which must have come from the north some 30 miles. Two others, one Oolite and the other Lias limestone, must have come N.E. distant 12 or 14 miles. Height above the sea about 280 ft.

Blocks at Newfound Pool, near ancient Roman Road, 'The Fosse Way.'—Some large blocks have been uncovered in the excavations for new streets at the above place, which is about $1\frac{1}{2}$ mile on the west side of the

town. All were in Upper Boulder clay, containing more sand than usual, which must have been derived from the beds below the Upper Keuper sandstone, which extends for some miles on that side of Leicester, the 'drift' varying from 6 ft. to as many inches in different places. The blocks were associated with a unique find (as far as this county is concerned), viz., a huge fin-bone, 2 ft. 6 in. long by 1 ft. 8 in. wide, of some species of whale. This was under about 4 ft. of drift of the Upper Boulder clay. Nearly all the animal tissue had been taken out of the bone, owing to its lying so little below the surface in the sandy drift. No other bones or teeth of the whale were found. It has been placed in the Leicester Museum.

Description of blocks :—

	Length.	Breadth.	Depth.
No. 1 . .	5 ft. 0 in.	× 3 ft. 0 in.	× 2 ft. 6 in. (sub-angular)
No. 2 . .	1 ft. 8 in.	× 1 ft. 6 in.	× 1 ft. 2 in. (angles very sharp)
No. 3 . .	1 ft. 4 in.	× 1 ft. 2 in.	× 1 ft. 0 in.

All syenite from Groby or Markfield, distant about 4 miles. Height above the sea 210 ft.

Report of the Committee, consisting of Professor VALENTINE BALL, Mr. H. G. FORDHAM, Professor HADDON, Professor HILLHOUSE, Mr. JOHN HOPKINSON, Dr. MACFARLANE, Professor MILNES MARSHALL, Mr. F. T. MOTT (Secretary), Dr. TRAQUAIR, and Dr. H. WOODWARD, reappointed at Manchester for the purpose of preparing a further Report upon the Provincial Museums of the United Kingdom.

THE Report of this Committee which was presented last year dealt mainly with the statistics of museums throughout the United Kingdom. The Committee was reappointed for the purpose of considering the ideal to which provincial museums should endeavour to attain, and of suggesting practical methods for approaching that ideal.

The provincial museums now existing may be classified roughly into the following six groups, viz. :—

1. Museums of Science and Art on a large scale, supported by Government, as at Edinburgh and Dublin.
2. Municipal Rate-supported Free Museums.
3. University Museums.
4. Teaching Museums attached to schools and colleges.
5. Museums belonging to local societies.
6. Proprietary Museums.

Of these typical groups the *first* must always be few in number, while the *third*, *fourth*, *fifth* and *sixth* have special objects, in pursuit of which they may properly diverge from any fixed standard.

The *second* type, the Municipal Rate-supported Free Museum, is already numerous, and is becoming annually more so. Its objects include those of all the others, and it may fairly be taken as a standard by which others may be gauged.

We propose, therefore, to consider what is the complete ideal which the authorities of a free rate-supported museum should keep before

them; not merely what is practicable under existing circumstances, but what would be the best under ideal conditions, and therefore what are the aims to be kept in view, and the lines upon which labour and money should be chiefly expended.

The general objects common to all museums are:—

1. To preserve, for the purpose of comparison and study, such specimens, whether of natural or artificial production, as may illustrate the history of the earth and its inhabitants.

2. So to arrange and display these specimens as to make them most available for such purposes.

The special objects of a free rate-supported museum in a provincial town should be:—

1. To contribute its share to the general scientific statistics of the country by collecting and preserving specimens of the natural and artificial productions of the district in which it is situated.

2. To procure such other specimens as may be desirable for illustrating the general principles of science, and the relations of the locality to the rest of the world.

3. To receive and preserve local collections or single specimens having any scientific value which the possessors may desire to devote to public use.

4. So to arrange and display the specimens collected as to afford the greatest amount of popular instruction consistent with their safe preservation and accessibility as objects of scientific study.

5. To render special assistance to local students and teachers of science.

Respecting the general objects of all museums, we do not think that there is much difference of opinion, and on this point little need be said. These objects, however, can be fully carried out only in such extensive buildings and with such large resources as are rarely attainable except in metropolitan cities. To represent the history of the entire inorganic world, and of the development and present condition of its vegetable and animal life, as far as these things are known to science, is an object worthy of a great State department but impracticable in any ordinary provincial town. Nor could even a State department hope to accomplish this work in full detail unless it could command much more extensive buildings and a much larger income than any nation has ever yet devoted to such a purpose.

What a national museum can practically do is to represent the history and present condition of the world and its inhabitants in an epitomised form, illustrating all the salient points and filling in the details of a few selected periods and types. It will also be the repository for important special collections and for very rare and costly objects which have a wide general interest.

In the series of specimens preserved in such a museum the national territory will be represented as a matter of course in its proper place, and in its due proportion to the whole. There may indeed be an additional department for that section of the earth's surface, with its geology, natural history, and archæology represented as a distinct group, and somewhat more elaborately than in the general collection; but to illustrate the full details of nature in the varied aspects presented by each parish and county, even within the limits of a single empire, would be impracticable in a museum devoted to the history of the world.

It is here that the provincial museums should take up the work, and should find their legitimate and most useful sphere. Every provincial museum ought, in the first place, to be a *fully illustrated monograph of its own district*. The details of each district can be worked up more thoroughly and more cheaply by the local museums than by any other agency, and if the entire history of the district and its inhabitants is thus represented, special attention being given to any group of objects for which the district is remarkable, this will be almost as much as any local institution can accomplish.

But science is daily becoming more exacting in its demands. Details which were thought ample in any provincial museum twenty years ago would now be regarded as quite insufficient.

In the department of geology every local variety of rock, with its fossils and its minerals, must be illustrated by specimens, by microscopic slides, and by chemical analysis; the stratigraphy and its relations to the physiography, the drainage, and the water supply, must be shown by diagrams, maps, and models, and careful records of every boring, sinking, and cutting, systematically procured and preserved.

In natural history the animal and vegetable life of the district must be represented in the most complete manner possible. There must be specimens of every indigenous animal from the highest vertebrate to the amoeba, and of every plant, including the lowest cryptogams, and at least those forms which are characteristic of the district must have their whole life histories illustrated by specimens of male, female, young in various stages, the skeletons and the nests or habitations of animals, and the soils and habitats natural to the plants.

The history of man in the district must be elaborately represented from the earliest pre-historic relic up to the latest phase, every local speciality of food, art, dress, customs, and language being recorded.

Thus much must be accomplished by every provincial museum if it is to 'contribute its share to the general scientific statistics of the country.' But if its collections are also to serve the purpose of interesting and instructing the local population, much more will be required.

For the purposes of general science, and for the use of experts, it is best to keep nearly all museum specimens in drawers and closed cabinets, protected from light, air, and dust; but for the instruction of the public a considerable number must be displayed in such a manner that they can be seen, studied, and compared without being handled. To do this involves without doubt the sacrifice of many specimens which will be destroyed in a few years by exposure to light and dust, and must be frequently replaced; and of much money which might be otherwise devoted to the furtherance of scientific investigation. This sacrifice, however, is absolutely necessary. The people who pay for the museum will insist upon its being administered for their direct and immediate benefit, as well as for their indirect advantage through the cultivation of science in its higher branches. And their demand is justifiable. It is as important to social progress that the millions should be educated as that the few should advance knowledge beyond its existing limits. The ideal Free Rate-supported Museum must do its best in both directions. While therefore a complete collection of all local specimens of a perishable nature must be carefully preserved for reference in closed cabinets, the imperishable ones, such as most geological and archæological objects, as well as duplicates of those perishable kinds which can be

readily replaced, must be displayed in glazed cases for the inspection of the public.

The difficult question here arises: In what manner shall this display be carried out so as to secure the maximum of instruction with the minimum of expense, and so as to make the museum attractive and interesting, yet not a place for mere idle amusement?

The Rev. H. H. Higgins, in his pamphlet on 'Museums of Natural History,' has pointed out that the public who visit museums may be divided into three classes, viz.: (1) Those who are already interested in science and come for information. (2) Those who have enough general culture to wish for more, and who come in the hope of learning something. (3) The very ignorant, who care only to be amused. To these classes he gives the appropriate designations of Students, Observers, and Loungers. Of the weekly visitors to a popular museum, the students probably do not form more than 5 per cent., the observers perhaps 75, and the loungers 20 per cent. It is obvious that, neglecting altogether the small proportion of loungers, a great deal may be done for the scientific instruction of those who come prepared to take intelligent interest in what they see.

The value of scientific instruction lies mainly (1) in the insight which it gives into the laws and processes of nature, thus greatly enlarging the mental purview; (2) in its training of the senses by the habit of accurate observation, and of the reasoning powers by the tracing out of causes and effects; (3) in its revelation of facts which may be turned to man's practical advantage.

In placing any scientific collections before the public with an educational object, all these points should be borne in mind. Accurate observation is to be cultivated chiefly by frequent comparisons of allied forms, and when a series of such comparisons reveals the lines of change, and the large effects of many small changes, the intellectual faculties are stimulated to investigate the forces which have been in operation.

Comparison, therefore, should be made easy, and the observer should be led up to the groupings and the lines of divergence in each department, and induced to look back into the past history and forward into the future prospects of the earth and its various inhabitants.

For these purposes it is not enough to place in the cases rows of specimens with their names and localities only. The natural groupings must be very conspicuously marked, and their points of connection and of divergence very clearly indicated. Attention must be drawn to the special characters of families, genera, and species, to geographical distribution, and to the varied aspects of nature in different localities.

The method of *labelling* in a public museum is of vital importance, and should receive the fullest attention of the curator. If a label contains too much, it will not be read; if it contains too little, its purpose is not effected. The titles of the large groups should be visible at some distance; their limits and their subdivisions should be so marked as to be very easily grasped by the mind of the observer. If Greek or Latin terms are used in these titles, English equivalents, wherever it is possible, should be added. Probably it is wiser at the present time to place the English first.

Nature draws no hard and fast line between the life of past ages and of the present epoch. The organic world is a continuous current, and to separate palæontology from biology cannot represent the actual facts in

their natural connection. Such separation may be convenient for students, but for the instruction of the public selected examples of fossil organisms should be in some manner associated with the living forms. It may not be easy to accomplish this, and it is not necessary that it should be done in any uniform method. Thoughtful curators who recognise the advantage will do the best they can with the means at their command.

The same may be said of the much-debated question—How best to display the forms of existing life? Methods may vary in detail, if the essential principles are carried out, viz., that comparison of allied forms must be rendered easy; that the grouping must be conspicuous; that the connections and divergences of groups must be indicated; that the labelling must be distinct and full; that as many of the facts of nature must be got into the allotted space as can be made clearly visible there, and that their practical bearing upon the wants of man must be shown, if possible.

Professor Herdman's phylogenetic system of arrangement has the great merit of presenting the life-groups in the true order of nature, as far as this is known. In a building suitable for such an arrangement, it would be an excellent scheme, and its leading idea should be borne in mind in all cases, but it could not generally be carried out in detail. Undoubtedly some orderly arrangement of groups should be adopted as a foundation in every museum. To have one room devoted to birds, the next to insects, and the next to fishes, would be wrong under all circumstances.

In considering the best form for cases and the best arrangement of the specimens, it must be remembered that the strength of every provincial museum ought to lie in its local collections. It is the special business of the local museum to collect the utmost possible amount of information respecting the locality, and as much of this should be laid before the public as can be made clear to them without risking the destruction of rare and perishable objects.

These local collections should form the central and most prominent display. Local objects can be obtained in the greatest abundance and at the least cost, and they will always have a peculiar attractiveness for the local public, who can best be instructed by being led from familiar objects of which they have some knowledge to those which are comparatively strange and unfamiliar, and which, if presented without such associations, would often be incomprehensible. Geological collections must be accompanied by maps, diagrams, sections, and models, so that the relation of each rock to the general series may be readily perceived. These maps, &c., may be of small size, but they are wanted in juxtaposition with the specimens, not hanging on distant walls, although, of course, large wall diagrams of a more general character are useful also. The building up of sections with slabs of the actual rocks has been adopted in some museums with very good effect. Such sections on a large scale erected in the surrounding grounds may give a good idea of the stratigraphy of the district. The relations between the rocks and the physiography, the drainage and the water supply, is best shown by relief models in clay, paper, or other material. In the display of minerals, their connection with various commercial products ought to be indicated. Throughout the whole of the geological department the results of chemical and microscopical analysis of the various rocks and minerals must be briefly stated.

Taking the local geology as the foundation, and confining to the local rocks the details above referred to, the relation of these to the known geology of the world requires to be very clearly represented. Specimens of all the principal strata not occurring in the district must be exhibited, and their absence from the district distinctly pointed out. To display a typical series of the rocks of the world in one line, and those of the district in a separate and parallel line, with the tablets or the labels of contrasted colours, is perhaps the best arrangement; but if space cannot be spared for this, a single line with differences of colour may be adopted.

In the geological department the arrangement must be chronological and stratigraphical. Each fossil-bearing rock must be accompanied by specimens of at least some of its characteristic fossils; in the case of local rocks these should be as numerous as space will admit.

In the natural history department a zoological arrangement will form the basis and the local species the principal display, the chronological evolution of these species being shown by duplicate fossils and drawings of extinct forms, and their relations to the fauna of the world by foreign types on a separate but parallel line as in the geological department.

It seems necessary that the vertebrates should be separated from the invertebrates. The immense difference in individual size and in the numbers of species compels a distinctly different method of display.

In each of these two great branches of zoology the same fundamental system must be adopted, viz., to give precedence to the local forms, to treat these in full detail, giving the utmost amount of information respecting them which can be satisfactorily shown within the given space, and to indicate their relations to the fauna of the world, and their evolution in geological periods.

The information which can be given to the public respecting the local forms of life will relate chiefly to their organic structure and their life-histories. The structure of invertebrates must be chiefly shown by drawings or models, and of vertebrates by skeletons. The life-history can be illustrated by specimens of the sexes, of the young in various stages, of the nests or other habitations, of the food, and of the habitats. If these, while remaining in their proper place in the series, can be grouped together in a pictorial manner so as to be fairly true to nature, the interest of the public will be greatly increased, additional instruction will be conveyed by them, and science will not suffer. But isolated groups are of much less value, and the tendency to set these up in a dramatic or artistic manner merely as sensational ornaments should be rigidly repressed.

It is of the first importance that the stuffing and mounting of vertebrates should be skilfully done. A large proportion of those at present displayed in provincial museums are mere delusions. They do not represent nature. An unstuffed skin is much more useful in every way than one which is set up untruthfully.

In the archæological and anthropological departments the same system must be carried out, but the arrangement here must be chronological.

Starting with the earliest relics of man discovered in the district, the series of examples of his work and habits should be continued even to the current date, particular attention being devoted to any local peculiarities. The changes which have taken place from age to age in his tools, his clothing, his architecture, pottery, ornaments, coinage, weapons, &c., as illustrated by purely local specimens, will be of the utmost interest and importance; and the whole local series should be supplemented by a few

examples of corresponding dates from various other parts of the world placed in a parallel arrangement for easy comparison.

The developments of the agriculture, the manufactures and the commerce of the district, will require to be exhibited in a distinct technological department, which, if well arranged, will be to a large number of visitors the most interesting and valuable part of the museum.

The botanical department is perhaps the most difficult to deal with in a public gallery. The herbarium in its usual form is scarcely available for the general use of the public, while collections of seeds, woods, and vegetable products, though of great value in themselves, give no insight into plant life. The modelling of plant forms is now carried to great perfection in decorative art. If typical plants of each order in the local flora were exhibited in this way, with corresponding examples of remarkable foreign species behind, and fossil forms in front, much interesting instruction would be afforded, and the cost would not be excessive.

Dried specimens of the whole local flora might well be exhibited in a cabinet of very shallow glazed drawers which the public could draw out but not remove.

The glass jar as now used for zoological purposes might be effectively applied to botanical specimens for the illustration of the life-history of typical species.

Provincial museums have made their collections hitherto in a very unsystematic manner, by donation or purchase as opportunities occurred.

In order that the scientific statistics of the country may be thoroughly investigated and made known as quickly as possible, a much more business-like system of collection should be adopted. The district should be divided into sections, and a paid collector appointed for each of them, whose whole time should be occupied for several years in obtaining specimens and records in every branch of science represented in the museum. In nearly every part of the kingdom competent men could be found to do this work for very moderate salaries. The necessary apparatus must be provided for them, they would generally require some amount of instruction, and during the period of their operations a sufficient staff of assistants must be employed at the museum to deal with the specimens brought in.

To carry out the work in this systematic manner, funds on a more liberal scale than is now usual must be provided for the first few years, but the value of the museum would be immensely enhanced, and when the local collections were made tolerably complete the permanent income required for maintenance would be very much less.

Taking, as an example, a town of 100,000 inhabitants, the centre of a district included within an average radius of ten miles, it may be roughly estimated that the cost of erecting a building thoroughly suitable for a museum, including the site and fittings, would not be less than 10,000*l.*, and that during the first three years an annual income of 1,500*l.* would be required, with a permanent income thereafter of not less than 600*l.* For smaller towns or smaller districts the estimate might be considerably less, but the penny rate authorised by the Public Libraries and Museums Act is insufficient to support both library and museum in one town on a satisfactory scale.

Every well-appointed museum should contain, in addition to its public galleries, an office for the curator, work rooms for the assistants, store rooms, a students' room with table, microscope, books of reference, and

a few chemical re-agents; and a keeper's residence. A residence for the curator, that he may be always on the spot, is desirable, if not essential; and, unless the town contains a separate college of science, a class-room, lecture theatre, and laboratory would be valuable additions. A library of standard scientific works, comprising not less than 500 volumes, is absolutely essential to the proper working of a museum. No curator can undertake to name and properly label the specimens collected without constant reference to books. All local scientific societies should be encouraged to hold their meetings at the museum, where a suitable room with lock-up cupboards might advantageously be provided for them, small rents being charged, except where this would involve the rating of the whole premises.

When donations are offered to a public museum the authorities should consider that they are concerned only for the public interest, and that they have no right to occupy space by the storage of objects which are of no public value. It is generally undesirable to accept any donations with restrictions as to what should be done with them. When they are given to the museum they become public property, to be dealt with freely for the public benefit. When presented they may be considered good examples of their kind, but if superior ones afterwards come to hand the authorities should have power freely to exchange or sell. Exceptions to this rule may be made in special cases. Collections brought together by eminent scientists often acquire a classical reputation and should not be broken up, or single specimens, even though of little value in themselves, may have a place in the history of science which should render them sacred. Such objects may be accepted under any reasonable conditions.

A movement has recently been inaugurated at York for bringing the curators of museums into closer communication and assisting in the exchange of duplicates. Something of the kind is much needed. A periodical publication, in which curators could from time to time describe portions of their duplicates, would probably be found useful. If it were possible to appoint a travelling inspector, who should devote his time to visiting the provincial museums in rotation, arranging exchanges, spreading the knowledge of new inventions in museum apparatus, assisting in the naming of doubtful specimens, taking notes of desiderata which might be supplied by other museums, and acting as a general medium of communication and consulting visitor, such an officer might be of very great service. An adequate salary would have to be provided, either by Government or by some independent society, with contributions from the museums visited. It might be difficult to find a man of sufficient tact, judgment, and knowledge who would undertake the post, but without doubt there is much to be done in this direction.

The town museum should be the place to which all students and teachers of science in the district should naturally go for assistance. To *bonâ fide* students every encouragement and facility should be given, and loan collections should be prepared for teachers. A system of travelling museums which circulate among the principal schools of the town has been adopted at Liverpool with great success.

The practical value of museums as important factors in all adequate systems of education is not yet recognised by the general public. Too many of these institutions have hitherto been but toys and hobbies, and require complete re-organisation. We are not aware of a single free rate-

supported provincial museum in the kingdom which has attained to the ideal recommended in this report.

In the first report of this Committee, published in the Manchester volume, the following corrections and additions should now be made, viz.:—

NOTE.—The pages refer to the Report as printed separately, not as in the volume.

Second Report of the Committee, consisting of Mr. R. ETHERIDGE, Dr. H. WOODWARD, and Mr. A. BELL (Secretary), appointed for the purpose of reporting upon the 'Manure' Gravels of Wexford. (Drawn up by Mr. A. BELL.)

NOTE.—In the following report it has been endeavoured to trace the nature, limits, and contents of, first, the so-called 'manure' gravels, their mode of occurrence and geological position; secondly, that of the sea-coast marls; and thirdly, the relations in which these stand to the drift deposits south of Dublin with which they have been correlated.

The fossils obtained have been transferred to the Geological Department, British Museum.

Nature of Ground.

Before entering upon the main purpose of this report a few words descriptive of the ground upon which the Wexford deposits rest may be desirable.

The bed-rocks of the district consist of purple conglomerates, slates, and sandstones of Cambrian and Cambro-Silurian age metamorphosed by the intrusion of vast masses of quartz rock into schists and felsites of varying hardness, and forming considerable elevations, upon whose summits the quartz stands out in precipitous masses. These elevations rise from the shore of the Slaney river, forming the ridge, upon part of whose seaward face Wexford city is built, to about 300 feet, and then descend rapidly before rising again to produce the Forth Mountain, a ridge extending 3 to 4 miles N.E. to S.W., with a height of 690 feet. A ridge of Palæozoic rocks also continued across the present Slaney valley to the north before the drainage of this part of Ireland was altered by the breaking down of a portion of it at Ferry Carrig, by Fitzstephen's Castle, forming the gorge of the modern Slaney river.

Between the Wexford and Wicklow Railway and the sea the ground rises into high hills and ranges, with occasional bog-lands at foot. Gneiss and granite are present at the extreme S.E. at Carnsore Point, and black calp limestones at Drinagh, near Wexford.

The later deposits of Wexford fall into three divisions, viz., (1) the so-called 'manure' gravel series; (2) marls and clays; (3) an illusory or fictitious drift. The first of these occur *only* on the *landward* side of the elevations and hills just referred to; the second on their *seaward* faces and cover in part the previous gravels; the third is forming wherever the bed-rock is exposed to atmospheric influences.

(i) The 'Manure' Gravel Series.

These consist in ascending order of fine sands passing up into a comminuted shell gravel covered by a débris of, for the most part, local rocks. Of these the sands are lowest and most persistent, appearing in the banks of the Slaney river, which has cut through them since their deposition. In a sandpit near St. Peter's College, Wexford, various igneous rocks, as quartz and granite, are present on the floor; but as in the side of the pit

near the top a large mass of felsite, one face measuring 2 feet or more, is *in situ*, pressing down and contorting the water-sorted gravel seams, these are doubtless not in their original place. The granite has probably come from the Carnsore horizon. Large transported rocks are, however, not common in these sands. From the shore at Artramon, on the eastern bank of the Slaney, all the way up the ascent to Castlebridge, the road exhibits this sand, which in a pit near Pulregan is beautifully exposed, passing up into comminuted shell gravel.

The section at Little Clonard is a very instructive one, and is the deposit referred to by earlier writers as being on the Forth Mountain. More accurately it is upon the land face of the Wexford ridge, *opposite to* the mountain. Down the slope of this ridge it extends for a distance of 150 yards, with a vertical thickness of about 20 to 24 feet. At the base of the section is a sheet of concreted or cemented gravelly sand a few inches thick. Upon this reposes a thick mass of sand with many pebble seams containing much small limestone, the fossils being most plentiful in these seams. Over this is a drift of stones very local in position, in some places absent, in others 3 feet thick. The upper beds having been much turned over during the 100 years the section has been open and the sand removed, no accurate idea can be conveyed as to the original condition of this portion of the pit; but in a continuation of the sheet of gravel a few perches away a pit has been opened within the last three years that may supply the deficiency. Here, below the surface soil, is a bed of clean sand with a brown marl 4 feet in thickness, this covering the fine limestone gravel. The larger drift is here absent, but may be seen further on the road in Mr. Moody's grounds at Rathaspick. The largest stones occur in the surface soil.

The next place where these shell gravels occur is on the side and top of the hill near Castlebridge at Pulregan; here the gravels are finer and sandier, and the local covering drift is less conspicuous.

For purposes of comparison with other deposits elsewhere, which have been considered as the equivalents of these gravels, a careful examination was made as to the nature and condition of this covering *débris*, and to this end the mean of several groups of twenty specimens, each picked at random from the face of the section, gave the following results:—

	Little Clonard	Pulregan	
		No. 1.	No. 2
Quartz and quartz rock	6	7	10
Cambrian or Ordovician	8	9	8
Limestone	5	1	1
Chalk flint	0	2	1
Granitic pebble	1	1	0
	<hr/> 20	<hr/> 20	<hr/> 20*

The examination of a heap piled at one side in Little Clonard pit yielded a larger proportion of quartz and Cambrian and less of limestone. At neither place did the stones bear those marks of glaciation, *striæ*, and polishing that occur in the limestone-drift proper. The pebbles are also more rounded.

Professor Harkness, 'Geol. Mag.,' vol. vi. p. 543, remarks on an exposure of these beds at Castle Ellis, about eight miles to the N.W. of Pulregan, that the sands and gravels are covered by a boulder clay 40 feet thick, 'abounding in angular, sub-angular, and rounded blocks,

chiefly Cambrian and Silurian, many beautifully striated.' This description so strongly applies to what I have termed an illusory drift that at present I am inclined to consider it a similar accumulation.

This is a drift, or rather a clay, resulting from the decomposition of the metamorphosed Palæozoic rocks wherever exposed to atmospheric influences. This is well seen between the Slaney and the Forth Mountain, and in and about Wexford, at Killurin and Macmine Junction, and almost everywhere at the foot of the hills along the railway line, wherever a cutting or excavation has been opened. This clay is full of blocks in various stages of degradation, occasionally covered and coloured by iron-froth. The soft nature of the metamorphosed Cambrian rocks renders their situation of less value in this point of view than if they were limestones.

The fauna contained in the gravels is very interesting; the only hitherto available lists are those made so many years back by Captain James and Professor Forbes, their usefulness being impaired by the uncertainty as to whether the fossils came from the gravel or the marl. I have therefore given in the following only those which I have obtained directly from the gravels, adding subsequently those of the earlier lists.

A large proportion of the shells are much abraded fragments, very few of the Pelecypoda being intact, the Gastropods suffering less damage.

The condition in which the remains occur does not altogether suggest more than a normal amount of violence or far removal, since equally broken fragments are to be seen in any ancient or modern sea-beach, such as the raised beach at Thatcher Island, or on the level stretch of sands at Paignton, both in Torbay.

Their distribution is rather capricious. Professor Forbes, *op. cit.*, p. 377, speaks of the abundance of *Purpura lapillus* and the presence of *Littorina littorea* as especially characteristic of the Wexford shelly gravels containing *Fusus contrarius*. These are rare in the southern parts of the district, where *Venus verrucosa*, doubtfully recognised by Professor Forbes as a Wexford fossil, is, on the contrary, not uncommon.

Many of the pits formerly open are now closed or water-logged. Kilbride, co. Wicklow, the locality given in the 'Fossil Catalogue' of the School of Mines, London, for some of Captain James' rarer fossils, has not been worked for forty years past, I am told by Mr Gawan, who has been resident there during that time, and directed my attention to one or two exposures of gravel. Only the local upper gravel with sand was visible. In the same manner as the Slaney in the south cut through the series since their deposition, so also has the Ovoca in the north, the Kilbride gravels being on the Wicklow side of the river.

(1) *Shells collected by A. Bell in the Wexford Gravels.*

Buccinum undatum.	Nassa incrassata.
Cypræa europea.	" reticulata.
Dentalium entalis.	" nitida.
Fusus gracilis.	" pygmæa.
" antiquus.	Natica greenlandica.
" contrarius.	Purpura lapillus.
" islandica jav.	" incrassata.
" Menapii, M.S. (n. sp.)	Pleurotoma pyramidalis.
Fissurella græca.	" rufa.
Murex erinaceus.	" (var. semicostata.)

Pleurotoma (var. Ulideana.)	Mya truncata.
„ turricula.	Mytilus edulis.
Trophon muricatus.	„ modiolus.
„ clathratus.	Nucula Cobboldiæ?
„ truncatus.	Ostrea edulis.
„ craticulatus.	Pinna.
Turritella incrassata.	Pectunculus glycymeris.
„ terebra	Pecten pusio.
Astarte borealis.	„ opercularis.
„ compressa.	„ maximus.
„ elliptica.	Solen marginatus.
„ (var. sulcata.)	Tapes decussatus.
Cardium edule	Tellina Balthica.
„ echinatum.	„ crassa.
„ rusticum.	• Venus casina.
Cyprina islandica.	„ verrucosa.
Mactra subtruncata.	Cliona.
Mya arenaria.	Balanus.

And several other forms still undetermined.

(2) *Species recorded by Captain James¹ not found by A. Bell.*

Aporrhais pes pelicani.	Trochus exasperatus.
Cypræa ? sp.	Trichotropis borealis.
Fusus crispus ?	Trophon Barvicensis.
Lacuna puteolus.	Anomia ephippium.
Littorina rudis.	Leda pusio ?
„ littorea.	„ pernula. •
Mitra (? cornea) ?	„ oblongoides ?
Melampus pyramidata.	• Mactra solida.
Nassa semistriata.	Nucula nucleus.
Patella vulgata.	„ proxima ?
Pleurotoma.	Pholas crispata.
Scalaria Trevelyana.	Saxicava arctica.
„ greenlandica.	Venus exoleta.

Of these a number are either extinct or only found in seas north or south of Britain, and such an association in the same area needs some explanation. The species are:

North—Astarte borealis, *Leda oblongoides, L. pernula, *Nucula Cobboldiæ, *N. proxima, Scalaria greenlandica, Purpura incrassata, Pleurotoma pyramidalis, Trophon clathratus, T. craticulatus, Meyeria pusilla.

South—*Leda pusio, *Cypræa sp., Turritella incrassata, *Nassa semistriata, *Mitra sp., *Pleurotoma, 2 sp.

Habitat unknown. Fusus (Menapii M.S.), F. n. sp., or allied to *F. crispus, Melampus pyramidata.

Those marked * are uncertain ascriptions according to Professor Forbes, and the Mitra, Nassa, Fusus, and Leda, like Captain James' notes, are no longer in evidence, being either lost or mislaid. Of Nucula Cobboldiæ, a living Japanese species, I have a rolled fragment, which seems to exhibit the peculiar sculpture of the shell. The Cypræa now (with Melampus) in the Museum of Practical Geology, London, requires confirmation.

The Mitre, according to Forbes, was an imperfect specimen, too

¹ *Journ. Dublin Geol. Soc.*, vol. iii. Some of these may have been obtained from the marls and not from the gravels.

much broken for identification of species; it might be either *M. greenlandica* or *M. cornea*, both of which Mr. R. A. C. Godwin-Austen, in 'The Natural History of the European Seas,' p. 262, states to occur here. This is, I venture to think, an error on his part.

Of the existence of the other species in the list there can be no doubt, and the question arises, by what routes did they come, and where do similar accumulations occur? On the latter point *Melampus pyramidata* is valuable evidence; its last appearance as a fossil occurring in Eastern England, in the Chillesford beds of Suffolk, in association with *Leda oblongoides*, *Nucula Cobboldiæ*, *Turritella incrassata*, *Scalaria greenlandica*, *Trophon clathratus*, and others in the list just given.

On the west coast of England it, in company with numerous other shells of southern origin and Pliocene age, occurs in the St. Erth valley in Cornwall, *Turritella incrassata* being a very abundant form; and the conclusion arrived at by the writer is that the Wexford series cannot be placed earlier than at or about the close of the Pliocene stage of East Britain, such as the Weybourn beds of Norfolk.

Professor Forbes was the first to suggest that 'there was a communication between the Mediterranean and the North Seas during this period.' Messrs. Dolfuss and Dautzenberg have also pointed out that the Cotentin deposit in North France is but an extension in continuation of the late Miocene seas.

The deposit at St. Erth¹ is evidently a further extension in a westerly direction, and a still further prolongation in a line northerly from St. Erth to the west of Carnsore Point would strike the valley between the Wexford ridge and the Forth Mountain, and continuing round the inland face of the hills already referred to reach the present coast-line just north of Arklow.

Such an extension would account for the presence of these southern species in the Wexford area. By what route the northern species arrived will be considered in the final report.

(ii) *Marls and Clays.*

On the survey maps it is said, 'The low lands of this coast and the interior up to a height of between 200 and 300 feet are covered by Pleistocene deposits, consisting of marls interstratified with sand and gravel containing arctic and other shells, chalk flint, pebbles of Antrim chalk, jasper, coal, and magnetic iron-sand.'

This description is not very definite, as the deposits vary much in character and are apparently of different ages. In Rosslare Bay, near Ballygeary, the lowest bed rests directly upon the base rock, and is a stiff black clay, originating from the black Carboniferous limestone a short distance away, and is only occasionally relieved by a few quartz pebbles, Cambrian rocks, or a limestone pebble or fossil. A bed of sand, more or less intermittent, ranging from three inches to three feet in thickness, separates this from an overlying very dark clay, with a few large stones and occasional seams of gravel. Fossils are present, but are fragmentary and difficult to find in the clay, but are better preserved in the pebble seams, from one of which, situated towards the top of the cliff to the west of the pier, the following species were obtained:—

Above this layer were embedded in the face of the cliff numerous land shells, such as *Helix hispida*, *Helix ericetorum*, &c. These may be of no great age. Traces of upland peat occur, and the freshwater *Limnea truncatula* is not uncommon, embedded in the cliff face.

The marine shells are also present in the railway cutting, and fragments may be noticed in the more friable clay or marl beds on either side of Wexford Harbour from the water level to some distance up the sides of the elevations already referred to. Near Wexford the clay becomes more sandy and yellowish, due probably to an admixture of the sands of the earlier series. Here traces of an old layer of oysters are visible. Elsewhere, as in the cliffs south of Arklow, it puts on the look of a rain-wash or brick earth, with few included rocks and without fossils.

The sand at Ballygeary yielded a broken *Trophon Barvicensis*, and the stiff black clay a fragment each of *Astarte sulcata* and *Pectunculus glycimeris*.

The only northern species obtained after close search were *Leda pernula* and, doubtfully, *Astarte borealis*.

Captain James described (1839) the cliffs at Ballygeary as consisting of dark tenacious clays, with rows of Nullipores. The only trace of this alga found was on a limestone pebble in the lowest clay, with a *Serpula* attached to it.

(iii) *The Coast from Delgany to Killiney.*

To ascertain what relations (if any) the Wexford series of deposits had to the so-called Lower, Middle, and Upper drifts of the Dublin area, it became necessary to examine the coast-line with some attention, from the rise of the cliffs at Delgany past Greystones to the sides of Bray Head, and thence to the granite boundary at Killiney and Dalkey, especially the fine exposure at Ballybrack in Killiney Bay, where, according to Professor Hull, the three sections are to be seen, as well as elsewhere. However it may be elsewhere, I was unable to detect any traces of an Upper drift; a conclusion I have since discovered was arrived at some years ago by Mr. G. H. Kinahan,¹ who, in discussing the question, states his opinion 'that there is no deposit between Killiney Hill and the Bray river that could possibly be called an Upper boulder clay drift,' as given by Professor Hull in the section in his paper upon Irish drifts.²

The older drift in Killiney Bay is made up of large and small rocks,

¹ *Geol. Mag.* vol. ix. p. 265 *et seq.* ('Middle Gravels of Ireland').

² *Ibid.* vol. viii. p. 295.

limestone, quartz, schists, and granites (many of the limestones being beautifully striated), intermixed with thick beds of sand, often tilted at an angle of 70° to 80° to the beach, beneath which they pass, reappearing at intervals near the Shanganagh and Bray rivers.

Resting upon, and in places overlying it, are the beds associated with the Middle drifts, made up of loose sands, gravel, and occasionally large blocks of granite and quartz, the cliffs gradually declining towards the south, where they sink to the shore a short distance north of the Shanganagh river. The upper portion of the section is composed of smaller gravel, and is so similar to the older drift that it is impossible to separate them, water action having mixed them together. The fossils in this horizon are chiefly confined to the lower portion of the section and are rather local in their distribution.

A shell-bearing gravel has been recognised for many years past as existing high up the Three Rock and Kilmashogue Mountains at elevations of 1,000 to 1,200 feet. Beyond the facts that these mountain gravels are largely limestone, and the shells all included in the fauna of the lower ones, there is nothing to connect the two. On the contrary, the shells, unlike the lower-lying species, are many of them scratched, and none of the arctic forms are at present known¹ to occur there.

The Shanganagh river flows by the base of a perpendicular cliff, about fourteen feet high, sloping rapidly from the coast inland. The base is a limestone drift (lower drift), passing upwards into a marly clay full of large, rounded granites, angular limestone blocks, and quartz rocks. Coastwise it is of limited extent, soon disappearing beneath the sandy marls referred to in the next section as occurring north of the Bray river. A few fragments of shell are present in the marl, which contains a few seams of pebbly gravel. It may be worth notice that where the marl is seen resting upon the limestone drift large blocks of granite abound, and limestone is almost, if not altogether, wanting. One out of a large number of granite blocks lying upon the shore I found to be 16 feet in circumference.

The shell gravels at Ballybrack have yielded an interesting series of fossils. I have, as in the case of the Wexford lists, given those collected by myself and then those obtained by other searchers not included in my own finds:—

Aporrhais pes pelicani.
Buccinum undatum.
Dentalium entalis.
 „ *Tarentinum.*
Fusus antiquus.
Hydrobia ulvæ.
 „ *ventricosa.*
Littorina littorea.
 „ *rudis.*
 „ *obtusata.*

 „ *verrucosa.*
 (Artemis) *exoleta.*
Balanus.
Fish vertebra.

Found by Canon Grainger (G.), W. W. Walpole (Appendix, Dr. Gwyn Jeffreys, 'Brit. Conch.' vol. v.) (W.), Professor Oldham (O.):—

Cypraea europea (G.).
Pleurotoma rufa (W.).
Trochus cinerarius (G.).
Loripes divaricatus (W.).

Mya arenaria (G.).
Psammobia vespertina (W.).
Woodia digitaria (W.).

A comparison of these lists with those given as from the Wexford gravels effectually disposes of the suggestion that the fauna of the two deposits are identical.

(iv) *From Delgany to the Bray River.*

In this district the cliffs rise from the shore a little S. of Greystones, and passing northwards thicken considerably, the deposits rising to more than 300 feet up the sides of Bray Head. The lowest beds at Delgany are limestone drift, containing the usual quartz, granite, and Cambrian boulders, capped by another gravel largely made up of Cambrian slates, micaceous schists, grits, quartz, and granitic rocks, Old Red sandstones, chalk flints, with comparatively little limestone. Yellow clay or marl, resembling a brick earth, occurs, at first sparingly, with seams of fine pebbles, thickening out northwards and infilling the hollows in the underlying beds. North of Bray Head it appears in the cliffs, dying out near the beach at the Shanganagh river, as already mentioned. South of Greystones, at the top of the gravel, a few fragments of *Mytilus modiolus*, with adherent epidermis and a portion of *Tapes virginea*, were the only fossils obtained.

Between Greystones and the Head the gravels overlies sands, to which they are presently seen to lie unconformable, the sands and pebbly seams beneath exposing strong current bedding, at an angle of about 20°, for a short distance, when an irregular mass of limestone débris appears, resting upon a thick bed of dark clay, with seams of sand and small gravel, exhibiting much contortion—even to the doubling of the seams upon themselves—the overlying débris pressing down into the hollows left by the contortions.

Evidences of water sorting are very prevalent all through the mass in the seams of pebbly sand which are interspersed in the drifts. Small fragments of shells are not uncommon in the gravel, especially in the rise above the line of railway before it enters the tunnel (*Astarte sulcata* and *compressa*, *Cardium echinatum*, *Tellina* and *Cyprina*), but are seldom determinable.

The like conditions are found north of Bray Head, where the gravel and bedded seams are seen to pass down to the sandy marls before mentioned. The bivalves just referred to are present here also, with a few pieces of *Purpura* and *Turritella*.

From the results obtained and described in the foregoing notes it would appear that—

1st. The Wexford gravel series proper are the sole remains of a series of sands and gravel deposited in an arm of the sea, occupying a channel opened out from a southern direction prior to the existence in this neighbourhood of the Slaney and Ovoca rivers, their fauna indicating their age to be immediately pre-Glacial.

2nd. That the gravel beds in Killiney Bay are of newer age,¹ and the contents do not bear out the suggestion that has been made as to their being coequal in time.

3rd. That the series of marls, clays, and brick earths of the coast had their origin and were formed subsequently under submersion, and are the newest deposits of all.

In a final report I propose to give a *résumé* of the Irish fossiliferous drifts in general, with a view to their bearings upon the distribution of the mollusca in other parts of Britain.

Report of the Committee, consisting of Professors McINTOSH (Secretary), ALLMAN, LANKESTER, BURDON SANDERSON, CLELAND, EWART, STIRLING, and MCKENDRICK, DR. CLEGHORN, and DR. TRAQUAIR, for continuing the Researches on Food-Fishes at the St. Andrews Marine Laboratory.

SINCE September 1887, the period included under the present grant, considerable additions have been made to the researches on the development and life-histories of the food-fishes. Thus the larval stages of the gadoids have been followed to the early post-larval stages, so that a fairly complete history, in several instances, can now be produced. Nevertheless it is true that in the earlier post-larval stages of the round fishes, it is difficult, *e.g.*, to distinguish between the cod, haddock, and whiting; at least this may be predicated of all the post-larval forms hitherto procured in May, the period when they first become conspicuous in the large mid-water net. It is only when the pigment assumes its definite character, for instance, the tessellated condition in the young cod, or when the barbel appears, and the fins become clearly outlined, that certainty is reached. In the case of the young cod, recognition is readily made on June 1, though the pigment has not yet assumed the distinctive tessellated condition; and the differences between this species and the young green cod at an early post-larval stage were also minutely examined this season.

Though it cannot yet be proved that a general migration of the young round fishes, *e.g.*, cod, haddock, and whiting, takes place from deep to shallow water, there are certain facts which bear upon such a habit. Thus, the post-larval cod are rarely met with on the grounds frequented by the adults, but appear in considerable numbers at a somewhat later stage in St. Andrews Bay, and in June at the margin of the tidal rocks at low water. As formerly mentioned, they increase in size as the season advances. Some remain for a year off the rocky coasts, and are caught

¹ Whether these Killiney gravels correspond to the Middle drift of the English and North Wales districts is not clear. I hope to trace the connection, if any, in the final report. At present the evidence is rather against than for such being the case.—A. B.

(as rock-cod) by hand-lines; while others of the same size, but having a less ruddy hue, abound at a somewhat greater distance from shore, *e.g.*, south-east of Girdleness in Aberdeenshire, and off the Bell Rock, and are caught in numbers by both liners and trawlers. The large cod frequent the deeper water at some distance from shore as a rule, though in pursuit of herrings they approach the shore more closely at certain seasons.

The post-larval stages of the haddock have hitherto escaped recognition; though G. O. Sars speaks of distinguishing the early post-larval haddock by their shorter and stouter form as contrasted with the young cod.

The life-history of the whiting has especially been elucidated during the year, and further additions made to the post-larval stages of the ling. It is interesting that two yellowish longitudinal bands occur along the sides of the former in the adult condition, especially in connection with the characteristic yellowish larval pigment. The development of the Clupeoids of the bay has also been followed, and observations made on their growth. The larval and post-larval stages of the sand-eel, so very abundant in the bay, have likewise been studied.

Amongst flat fishes (Pleuronectidæ), the post-larval stages of the common flounder, the long rough dab and other forms, have been examined, and their life-histories followed more or less completely. The eggs apparently of the sole have been found late in summer near the surface of the bay, and though the adults are few, there is no reason why they should not be increased by artificial aid, such as the introduction of a number of adults from Scarborough and other convenient localities. The food of the sole is very abundant in St. Andrews Bay, and the only difficulty will be competition with the hardy plaice so numerous in this ground. The post-larval stage apparently of the turbot was procured towards the end of August, and is remarkable for its peculiar yellowish coloration. Several unknown eggs probably belonging to the same group (Pleuronectidæ), and which were first met with in the trawling expeditions of 1884, were also again observed, and further steps made to their identification.

A post-larval *Labrus maculatus*, 11 mm. in length, procured by the mid-water net in September, showed some interesting features in coloration, the chief being a series of white touches on a greenish ground, with brown bands on the head. The soft rays of the dorsal fins have not yet attained the proportionally elongated condition of the adult organ. The pectorals are large, and their rapid vibratory movement resembles that of *Hippocampus* and the Sygnathidæ. A brown bar marks their basal region, which in this and many other post-larval fishes is much larger in proportion than in the adult—a condition probably connected with increased functional activity. The ventral fins are opaque white, with a brownish belt in front (anterior rays). The anal fin, like the dorsal, has a brown patch in front. None of the blue, yellow, or orange, so common in the adult, has yet appeared.

Additional observations have also been made on the spawning period of various fishes about which little is at present known, such as the bass, Yarrell's blenny, wrasse, &c. Remarkable cases in which mussels (*Mytilus edulis*) have grown to a considerable size on the branchiæ of the haddock have likewise been observed.

Besides the food-fishes, further advances have been made on the development of the gunnel, the adults of which remain with their ova in holes (*e.g.*, those bored by *Pholas*) in rocks, and on the larval and post-

larval stages of *Agonus*, *Motella*, and other forms. The early post-larval stage of *Agonus* is peculiar from its fusiform outline and yellowish coloration. The former is due to the great median development of the marginal fin dorsally and ventrally. The post-larval condition of *Liparis montagui* has likewise come under notice when about 10 mm. in length. The notochord still projects superiorly from the tip of the tail, and the hypural edge is almost vertical. The caudal region, with its fin-rays, is bluntly conical. A marked feature is the elevation of the first region of the dorsal fin and its wider rays, a differentiation, perhaps, indicating the relationship with a form in which such is present in the adult. The head and cheeks have a few black specks, and these also occur on the anterior region of the body. The pectorals are speckled in a similar manner. The elongated rays of these fins are not yet developed, so that this is a subsequent character. Their margins trend evenly from the anterior part of the sucker backward and upward. The difference in regard to the size of the eye of such a species as this and one of the post-larval gadoids is marked, the large eyes of the latter being diagnostic, and probably associated with their greater adroitness and activity in catching minute prey.

The researches on the development and life-histories of the food- and other fishes made by the Secretary (Professor McIntosh) and Mr. E. E. Prince, B.A. (Cantab.), comprising upwards of 400 pages MS. and 31 quarto plates, containing many coloured figures, have recently (June 18) been communicated to the Royal Society of Edinburgh.

A special research was carried out by Mr. E. E. Prince on the Morphology of the Limbs of Teleosteans, and illustrated by three quarto plates. This work, like that already published or about to be published, reflects great credit on its author, both for the careful nature of the observations and the beauty and accuracy of the drawings.

Another investigation, no less able, is that of Dr. Marcus Gunn, M.A., M.R.C.S., one of the surgeons of Moorfields Hospital, London, on the Embryology of the Retina of the Teleosteans. A preliminary paper on this important subject appears in the 'Annals of Natural History' for this month (September).

Professor D. J. Cunningham, M.D., M.R.I.A., is also engaged on the Development of the Teleostean Vertebral Column; while Professor Burdon Sanderson and Mr. Gotch¹ carried on during the summer an investigation (in the living skate) of the caudal electrical organ. Many embryo skates have since been sent to Dr. Minot of America and Professor Ewart for microscopic purposes in connection with this research and other investigations. Mr. Kennedy, B.Sc. of Glasgow University, also spent a few weeks in working at the development of the haddock, and Mr. Grabham, B.A. of Cambridge, a similar period in examining the spinal nerves of the cod.

One of the most interesting results of the steady use of the mid-water and other nets for some years in St. Andrews Bay and elsewhere has been the testing of the Pelagic life at various seasons, so as to elucidate the nature of the food of the post-larval food-fishes, and also throw light on other questions. For the year 1888 the continuation of this work has been specially undertaken for the Fishery Board for Scotland, and will therefore be dealt with elsewhere. Independently, however, of the bearings of the fauna and flora (diatoms, &c.) on the food of fishes, some remarkable forms have come under notice, and the growth and habits of

¹ Vide *Proc. Roy. Soc.*, 1888.

others less rare have also been periodically noted. No group is more interesting in this respect, perhaps, than the Ctenophores, and certainly none is more abundant. Besides the ordinary forms at all stages, a new British species, viz., *Lesueuria vitrea*, M. Ed., has been procured in St. Andrews Bay in great profusion and for an extended period. The examples ranged from the most minute up to those $2\frac{1}{2}$ inches in length, but of all the British Ctenophores, or even Medusæ, it is the most delicate. The mere pouring of the water containing it from one vessel to another is sufficient to rupture it irretrievably, and indeed any undue commotion in the water has the same effect. It is well known as an inhabitant of the Mediterranean since it was originally described by Milne Edwards, and it has also been found on the American coast by Alex. Agassiz. An allied form, again, was procured on the shores of Norway by M. Sars.

During this summer, also, the great abundance of the ecto-parasitic larvæ of *Peachia* on *Thaumantias* has been a conspicuous feature, and many have been preserved for the further researches of Professor Haddon, M.A., D.Sc., M.R.I.A., who this month (September) contributes an interesting paper on the subject to the 'Annals of Natural History.'

In the winter, numerous examples of the common star-fish (*Asterias rubens*), brought from the bay on the lines of the fishermen, showed many ecto-parasitic crustaceans (*Podalirius typicus*, Krøyer): These generally adhered by the posterior legs, with their bodies projecting at right angles from the rays of the star-fish. In previous descriptions of this form the habitat seems to have been overlooked, for Spence-Bate and Westwood simply state that it was procured in the Forth, upon a shell brought up by a haddock-line, and in the recent catalogue of the Mediterranean Fauna¹ no allusion to commensalism occurs.

Further observations have also been made on the development and life-history of the common mussel, which forms a valuable 'bed' in the estuary of the Eden. These have chiefly been carried out by Mr. John Wilson, B.Sc., who lately published an important paper with four quarto plates on the subject in the Fifth Annual Report of the Fishery Board for Scotland.²

Mr. Herbert E. Durham, B.A., lately Vintner Exhibitioner at Cambridge, continued the interesting researches of last year on the Amœboid corpuscles in the star-fish, and also on the madreporite of *Cribrella sanguinolenta*.³

Besides the use of the yacht 'Dalhousie,' the services of the steam tender 'Garland' were placed at the disposal of the Secretary for some days by the courtesy of the Fishery Board for Scotland for work in the deeper water at a distance from shore. Certain well-known fishing and

¹ *Prodromus Faunæ Mediterraneæ*, pars ii. p. 390, 1885.

² Previous to a lecture on this subject in the University of St. Andrews in November 1883, the Town Council requested the convener to give a report dealing with the preservation and increase of the mussel-beds of the Eden. The work for H.M. Trawling Commission, however, supervened, and occupied the whole of the following year. Thereafter the subject was steadily kept in view, as indicated in the Third Annual Report of the Fishery Board (1885, p. 57). A short abstract was also published in the *Annals of Natural History* for February 1885. It being apparent that a thorough knowledge of the development and life-history of the species was indispensable for advancing the subject on a sound basis, Mr. John Wilson took up this portion of the work, his observations being published in the Fourth Annual Report of the Fishery Board (1886, p. 218), and next year in the Fifth Report with three quarto plates (1887, p. 247).

³ *Proc. Roy. Soc.* January, 1888.

trawling grounds were thus examined in connection with the observations on the development and life-histories of the food-fishes.

Considering the importance of the work in relation to our knowledge of the food- and other fishes, and the advances in Invertebrate Zoology, the Committee beg to recommend a renewal of the grant (50*l.*) for the ensuing year.

Fourteenth Report of the Committee, consisting of Drs. E. HULL and H. W. CROSSKEY, Sir DOUGLAS GALTON, Professor G. A. LEBOUR, and Messrs. JAMES GLAISHER, E. B. MARTEN, G. H. MORTON, W. PENGELLY, JAMES PLANT, J. PRESTWICH, I. ROBERTS, T. S. STOOKE, G. J. SYMONS, W. TOPLEY, TYLDEN-WRIGHT, E. WETHERED, W. WHITAKER, and C. E. DE RANCE (Secretary), appointed for the purpose of investigating the Circulation of Underground Waters in the Permeable Formations of England and Wales, and the Quantity and Character of the Water supplied to various Towns and Districts from these Formations. (Drawn up by C. E. DE RANCE, Reporter.)

THE drought to which your Committee drew attention in their report last year was continued up to June of the present year, and had a very marked influence in diminishing the volume of water yielded by a large number of springs, and a very considerable diminution of the supply afforded by the remainder, over the greater portion of the central area of England, an area in which underground stores give the larger proportion of the daily water-supply of the population.

Much useful information has been obtained as to the amount of diminution experienced, but it has been thought advisable to combine it with information now being collected, showing the effect of the recent heavy rains in re-charging the underground stores.

Statistics of this nature collected during the past season, probably the most exceptional season of the present century, will necessarily have a permanent value in future calculations as to the actual yield likely to be obtained from a given area after successive years of minimum rainfall.

It has been thought advisable to defer publishing the information already obtained until next year, when it can be given in a more complete and useful form. Your Committee hope that the attention of the Delegates of the Associated Scientific Societies may be drawn to the importance of this inquiry, and that local observers will give special attention to the date at which the springs of their neighbourhood diminished in yield and subsequently increased; the date at which any springs ceased to flow, and that on which they recommenced; the amount of flow of any springs either daily, weekly, or monthly; similar records of the heights of the water in wells and borings, whether for long or short periods. The value of such observations would be much enhanced if descriptions be given that will enable the locality to be identified on the one-inch map of the Ordnance Survey and the levels referred to the Ordnance Datum.

Your Committee seek re-election, but do not require a grant to carry on their investigations.

1888.

L

*Report of the Committee, consisting of Mr. JOHN CORDEAUX (Secretary), Professor A. NEWTON, Mr. J. A. HARVIE-BROWN, Mr. WILLIAM EAGLE CLARKE, Mr. R. M. BARRINGTON, and Mr. A. G. MORE, reappointed at Manchester for the purpose of obtaining (with the consent of the Master and Brethren of the Trinity House and the Commissioners of Northern and Irish Lights) observations on the Migration of Birds at Lighthouses and Lightvessels, and of reporting on the same.*¹

ALTOGETHER about two hundred lighthouses and lightships on the coasts of Great Britain and Ireland, and the outlying islands, were supplied with printed tables for recording the movements of migratory birds. The collected results of the observations have been again published by the Committee in their ninth report. There has been a considerable increase in the number of schedules sent in, and it is satisfactory to note that the majority of the returns show increased care, and much intelligent interest on the part of the observer.

Commencing with the east coast of Scotland, Mr. John Nichol, the principal of the North Unst Lighthouse, reports that several pied-ravens, presumably visitors from the Faroes, were seen in June and July near Lerwick; one of these had white wings, another with white head and tips of wings, others also variously marked.

At the Pentland Skerries a girl-bunting was obtained on November 2. This species has only been recorded four or five times in Scotland, and never so far north in the country.

At the same period there was at this station a large 'rush' of fieldfares, redwings, thrushes and blackbirds, gold-crested wrens, snow-buntings and woodcocks with a south-east wind. A hoopoe was also seen on October 9.

Between the middle of August and up to October several pied-flycatchers are also recorded at Pentland Skerries.

A considerable number of schedules from the chief stations on the east coast of Scotland have been filled with the movements of the gannet, and these, with other accounts already published, will, at some future date, constitute materials for a thorough treatment of the wanderings of this species, and their relations to the migration of the herring in the northern seas.

The number of schedules sent in from thirty-four stations on the east coast of England was eighty-four.

After January 2 depressions of a very considerable size passed by our north-western and northern shores, with sudden changes of temperature of an unusual character, and great magnitude; showers of cold rain, sleet and hail, from day to day, and very severe frosts at night. There are very clear indications in the diary of migration that a 'great rush' of birds, going southward along the coast, was concurrent with these atmospheric disturbances. The birds chiefly noted being fieldfares, blackbirds, thrushes, redwings, larks, chaffinches, linnets, starlings, and some crows.

¹ 'Report on the Migration of Birds in the Spring and Autumn of 1887.' McFarlane and Erskine, 19 St. James's Square, Edinburgh.

In the latter part of February and throughout March there are indications of the passage of crows, rooks, daws, starlings, larks, and others to the Continent; also the same species moving in the reverse direction to the south-east coast of England. Great numbers of starlings, thrushes, and larks were observed at the lanterns at night, showing that the movement was very general and of very considerable extent.

A remarkable 'rush' of the smaller summer visitants occurred on the south-east coast, from Thanet to Hunstanton, at early morning of April 29. A very strongly-pronounced movement was also observed at Hanois L. H., Guernsey, on May 2, and on the 3rd and 4th. There were extraordinary 'rushes' of summer immigrants at the Eddystone and Nash stations; and at Helwick L. V., South Wales, on the 5th, when wheatears, whitethroats, sedge-warblers, willow-wrens, wood-warblers, blackcaps, reed-warblers, redstarts and pied-flycatchers, and also some swallows, were killed, some of these in considerable numbers; the weather at the earlier period, April 29, being very rainy and unsettled in the south-east, and very cold over England, with north-east winds. On the 30th, there was a thunderstorm in the south-west of France, with very cold, unsettled, and rainy weather generally in the south of Europe.

The autumn movement of birds commenced early in July, but did not become very distinctly pronounced before the beginning of August. One of the most interesting features of the autumnal migration has been the simultaneous occurrence of the pygmy curlew (*Tringa subarquata*) and the little stint (*T. minuta*) on the coast, between the Tees and Yarmouth. The former is first recorded from Redcar on August 16, and from the Spurn on August 23; the little stint on the 25th.

The woodcock is first recorded at Seaton-Carew, Durham, on September 19, and at Cromer L. H. on the 25th from 12.30 to 2.30 a.m. (S.E. 4). Our observer, Mr. Comben, says, 'I never saw so many woodcocks at one time before; there seemed to be a constant stream flying round the lantern; none struck.' Woodcocks appear to have come in at irregular intervals between September 30 and November 3, the great 'rush' or flight, on the 9th, 10th, and 11th of October. It is somewhat remarkable that the only notice of this species on the east coast of Scotland occurs at the Pentland Skerries and Dunnet Head L. H., Caithness, early in November and again in December.

Throughout September there was a steady, and almost daily increasing, migration observed at the east coast stations, and from the 29th, throughout October, and to November 3, an almost continuous night and day rush of immigrants, the chief of those recorded being crows, rooks, daws, starlings, larks, chaffinches, linnets, and sparrows; much the greater proportion of the entries in the schedules during this period consisting of these readily distinguishable species. The weather during the period of this great and continuous 'rush' was up to October 25 mainly anti-cyclonic, cold, quiet, and dry; the prevailing winds, north and north-easterly; after the 25th, cyclonic, with west and south-westerly winds, wet, rough and milder. The average temperature of the month was much colder than the corresponding months in the two preceding years. There is no evidence that the change of weather and of the wind after the 25th had the slightest influence in controlling the migratory movement, birds continuing to arrive in undiminished numbers.

The direction and force of the wind at the time appear to have little effect in controlling the great autumnal 'rushes,' for when the period of

the year has arrived birds cross the North Sea independent of weather. There can, however, be no doubt that the prevailing wind at the time of crossing is an important factor in governing the direction in which migrants travel, and the angle at which the line of flight will intersect the coast. To changes of temperature, either sudden or more gradual, rather than the force and direction of winds, we must probably look for the impelling cause of these seasonal phenomena. After the 3rd and to the 19th of November birds continued to arrive, but in greatly reduced numbers, the throbs and pulsations of the great inrush becoming daily more feeble and less sustained.

On the west coast of England migration, although considerable in October, was more strongly pronounced in November, particularly from the 7th to the 19th. On the afternoon of the 11th an anti-cyclonic period commenced, and prevailed, with little break, until the 17th. And there were important general movements on the 11th, 13th, and 14th, and on the 17th and 18th at south-west stations.

The entries in the schedules show that swans and geese have been remarkably scarce, brent geese fairly numerous—ducks of various species have occurred in unusually large numbers in all favourable localities. The common scoter in enormous flocks, also several velvet scoters, and very considerable numbers of the long-tailed duck have visited the coast between the Farn Islands and Yarmouth. A bearded reedling (*Panurus biarmicus*) was seen at the Languard L. H. on February 16, at 7.40 a.m., and at Yarmouth on November 13 many are said to have come in at a great height from the east.

Amongst the rare and more interesting wanderers to our shores we may notice the occurrences of Temminck's stint at the Spurn and the eared-grebe at the same place, Richard's pipit on the Lincolnshire coast, the Alpine swift, avosets, and the pectoral sandpiper of America near Yarmouth, also an osprey obtained at the Cromer Lighthouse. The isabelline wheatear, a spring visitor from the south to south-eastern Russia, was shot at Allonby, Cumberland, on November 11.

From the Irish coasts the schedules received from the light-keepers in 1887 were perhaps the best and most carefully filled of any year so far. They number about 70 besides many letters inquiring the names of particular species or remarking on special movements of birds. These have been furnished by about 30 stations situated all round the Irish coast. Over 150 legs and wings and specimens in the flesh have been received, being a larger number than on any previous occasion. This is satisfactory because the species can be ascertained with certainty.

Two birds have been added to the Irish list, i.e., the Lapland bunting and the red-breasted flycatcher. The former was found dead at the Fastnet Rock Lighthouse, October 16; the latter was killed striking the Arklow South Light-ship on October 23. Both specimens were forwarded in the flesh. A magnificent old male *Falco candicans* was shot by the light-keeper on the Great Skelly Rock, co. Kerry, on September 28. This bird is occasionally met with on the west coast of Ireland at light-stations, and the inquiry has shown that it occurs more frequently than was formerly supposed.

Among other rarities received may be mentioned a redstart from the Fastnet (a rare species in Ireland), killed October 5; a woodlark and spotted crake from the Tearaght Rock, co. Kerry, also killed in October; and a hoopoe from Eagle Island, off Mayo (April 12).

Of the warblers the sedge warbler strikes the lanterns more frequently than any other, but the western and northern stations are almost a blank, few warblers striking.

The great bulk of the summer migrants arrive in Ireland on the south coast and the southern portion of the east coast below Drogheda.

During the second and third weeks of November the waterrail was forwarded from stations all round Ireland. It has not occurred in such numbers before.

A large immigration of the siskin and brambling took place in October and November. These birds have seldom been received from the light-keepers until 1887.

The autumn rushes of most species were on a larger scale than usual in 1887, and both summer and winter migrants seem to prefer the south-east portion of Ireland when arriving. The snow-bunting is one of the few birds which is rarely met with during the season of immigration on our south-east coasts.

The woodcock seldom strikes the lanterns anywhere.

So far as waders are concerned there is no clear evidence derived from the light-stations to show that they arrive in greater numbers on our northern stations in the autumn than on the south-east and south coasts.

This inquiry has now been continued for nine years, and an immense number of facts have been collected and brought together in the Annual Reports in connection with the seasonal movement of birds on the British coasts. The value of the materials thus acquired has been very considerably increased by the wings and legs sent in from the lighthouses and lightvessels of birds killed against the lanterns. Your Committee are aware that if this inquiry is to lead to any practical scientific results, much yet remains to be done; they would, therefore, respectfully suggest that the collection of further facts and materials should for the present be suspended, and an attempt rather be made to utilise, digest, and classify the mass of information already at their disposal. This your Committee are anxious and willing to undertake, and have already made arrangements for carrying into effect, so as to show in a concise form the results both statistically and otherwise on strictly scientific lines, and in as condensed and clear a method as possible.

The Committee have much pleasure in stating that one of their number, Mr. William Eagle Clarke, of the Museum of Science and Art in Edinburgh, has undertaken the laborious task of thus reducing the mass of observations collected. This will not be executed from the reports already published, but from an examination *de novo* of the schedules sent in. When it is accomplished, the question of publishing the results will arise, and the Committee trust that, if necessary, the aid of the British Association may again be successfully invoked. The Committee are quite sensible of the liberality with which the Association has for so many years responded to, and even more than once anticipated, their demands, and have to express their gratitude for the generosity not only of the Association, but of private individuals towards their investigations; but the Committee must point out that the crowning work has yet to be done, and, while abstaining at this time from any application for pecuniary help, they hope that it may be forthcoming, if required, at some future date.

Report of the Committee, consisting of Professor W. C. WILLIAMSON and Mr. W. CASH, appointed for the purpose of investigating the Flora of the Carboniferous Rocks of Lancashire and West Yorkshire. (Drawn up by Professor W. C. WILLIAMSON.)

As I had occasion to report to the Association at Manchester last year, much labour has now to be expended in order to reap a very small harvest. Our many years of persevering research have well-nigh exhausted the supply of the more conspicuous facts connected with the organisation of the Carboniferous vegetation. At the same time there is still much respecting which more information is needed, and the work of the past year has not been devoid of some important observations.

One of the most curious structural and physiological facts revealed by the study of the exogenous Carboniferous Cryptogams relates to the development of their conspicuous piths. This is especially the case amongst the arborescent Lycopodiaceæ. I have from time to time called attention to some curious facts bearing upon this matter: I have shown that in the young twigs of some of these plants the central vascular bundle, corresponding to what the late Professor De Bary would designate as the 'leaf-trace' in contradistinction to a Cauline one, is composed of a number of scalariform vessels, as is the case with the twigs of many of the living Lycopodiaceæ. But unlike these living representatives of the group, there lurked in the centre of each of these palæozoic bundles, an invisible germ or germs of a parenchymatous tissue which developed as the plant grew, and ultimately expanded into a conspicuous, persistent pith of large dimensions; not only so, but portions of this medullary tissue assumed the functions of a Cambium by developing additions to the vascular ring by which it was surrounded. Botanists will at once recognise the differences between this mode of development of a medulla and what occurs amongst ordinary living Exogens.

Some of my most important results obtained during the past year consist of new facts relating to this curious physiological and morphological feature of the Palæozoic Flora; explanations which I previously advanced hypothetically now assume the appearance of unquestionable truths. Hence I believe I am now in a position to publish what I hope to do with little delay, viz., a fairly complete history of the anomalous development of these palæozoic medullary organs.

Report of the Committee, consisting of Professor RAY LANKESTER, Mr. P. L. SCLATER, Professor M. FOSTER, Mr. A. SEDGWICK, Professor A. M. MARSHALL, Professor A. C. HADDON, Professor MOSELEY, and Mr. PERCY SLADEN (Secretary), appointed for the purpose of arranging for the occupation of a Table at the Zoological Station at Naples.

YOUR Committee have to report several notable advances in the scope of the Zoological Station, which give promise of important results in the future.

The past year has been marked by the opening of the physiological laboratory, which occupies a new and handsome building adjacent to,

and nearly as large as, the original Station. The progress of the work has been mentioned in several previous Reports; and the Direction is now to be congratulated on the completion of this costly undertaking. Most of the rooms are already occupied.]

A bacteriological laboratory, which is placed under the direction of Dr. Frank, formerly assistant to Professor Koch, was opened on May 1. This department, which is especially maintained by Italian contributions, and is intended to promote a knowledge of marine bacteria, will in the first instance co-operate with the local efforts to investigate the sanitary condition of the Port of Naples and the neighbouring coast. Two or three naturalists are now devoting themselves to these researches.

The chemical department of the physiological laboratory has been completed under the direction of Dr. W. v. Schroeder, of Strasburg, who has previously carried out physiological investigations at the Station. Several universities and states are already taking an interest in this department—a circumstance which it is anticipated will contribute towards the success as well as the support of the new branch.

Investigations of a practical bearing on the fishery industry, carried out primarily at the instigation of the Italian Ministry of Agriculture and Commerce, have been prosecuted with energy. An important memoir on the question of the propagation of fishes and the nature of their ova has been published in the 'Mittheilungen' and the official 'Bulletin,' by Dr. Raffaele, of Naples, one of the assistants in the Station. Special arrangements have been made for these studies in the new building and the researches are being carried on actively. Additional proof of the urgent need of such practical investigations was furnished by an agitation on the question of trawl-fishing, which was got up last year in Naples and the neighbourhood, and resulted in numerous contradictory demands being addressed to the Ministry upon the subject.

Several officers belonging to the Italian and Russian navies have received instruction during the past year in the methods of collecting marine animals and plants. These gentlemen are now embarked on men-of-war, and interesting results may be anticipated from the labours of collectors thus thoroughly qualified.

During the past year two tables have been taken by Austria. This circumstance is especially significant, as hitherto when applications were made either by Austrian naturalists or by Professor Dohrn himself to the Austrian Government, soliciting the engagement of a table in the Naples Station, the applications have been rejected on the ground that the existence of a zoological station at Trieste rendered it unnecessary for Austria to lease a table in the Naples Station. It was urged against this argument that the Naples Station ought to be considered as a central institution, and that whatever local institutions might be founded, the international character of the Neapolitan establishment rendered it not only desirable but necessary to secure a footing there. At last two tables have been taken, in consequence of a collective requisition made by the four Austrian universities, in which it was stated that in spite of possessing a zoological station at Trieste the participation of Austria in the Naples Station was still desirable; its highly-developed organisation, the richness of the local fauna, the excellence of the library, and the association there of scientific workers from all countries, rendering such a participation necessary in the interests of Austrian naturalists.

Negotiations for securing three tables for Spain are proceeding, and

a royal decree charging the Ministry with direct propositions to Professor Dohrn has been published.

The Publications of the Station.—The progress of the various works undertaken by the Station is here summarised:—

1. Of the 'Fauna und Flora des Golfes von Neapel' the following two monographs have been published since the last Report:

XV. G. von Koch, *Gorgonidæ*.

XVI. H. Eisig, *Capitellidæ*.

The plates for the following works are in the press: Falkenberg on 'Rhodomeleæ'; Spengel on 'Balanoglossus'; Della Valle on 'Amphipoda'; Giesbrecht on 'Copepoda'; and Vosmaer on 'Porifera inalcarea.' The text for the last-mentioned work will be in English.

2. Of the 'Mittheilungen aus der Zoologischen Station zu Neapel,' vol. vii., parts ii., iii., and iv., with 24 plates, have been published.

3. Of the 'Zoologischer Jahresbericht' for 1885, parts i. and iv. and a 'Nachtrag (Vermes)' have been published; and the whole 'Bericht' for 1886 (dealing no longer with systematic and faunistic papers).

Extracts from the General Report of the Zoological Station.—The officers of the Station have courteously furnished lists (1) of the naturalists who have occupied tables since the last report, (2) of the works published during 1887 by naturalists who have worked at the Zoological Station, (3) of the specimens sent out by the Station during the past year. These details show a large increase in the number of naturalists who have worked at the Station, as compared with any previous year, and an increase also in the total value of the specimens distributed.

The British Association Table.—Three naturalists have occupied the British Association Table during the past year. Mr. John Gardiner, who had occupied the table for five months during the preceding year, was still in possession at the commencement of the past year, and had intended to occupy the table until December, in accordance with the permission of your Committee. Unfortunately a dangerous illness prevented the carrying out of these intentions, and the climate of Naples being considered unsuitable for Mr. Gardiner's restoration to health, he was obliged to resign the table after occupying it a little more than two months in the year with which the present report is concerned. Mr. Gardiner sent an interesting report on the result of some of his work to the Committee, which was submitted at the last meeting of the Association, and the supplementary report on the remainder of his occupation, which Mr. Gardiner has sent from Colorado, will be found appended.

The use of the table has been granted during the past year to Mr. Andrew David Sloan, of Edinburgh, and subsequently to Professor R. J. Anderson, of Queen's College, Galway, both of whom have furnished reports on the nature of their investigations. The reports are appended.

Your Committee have received two applications for permission to use the British Association table during the current and coming year, which they approve; and hope that the Council will enable them to sanction the applications by renewing the grant (100*l.*) for the ensuing year. In the opinion of your Committee the report now submitted fully justifies them in strongly recommending the renewal of the grant.

I. Report on the Occupation of the Table, by Mr. JOHN GARDINER.

Soon after the date of my last report, I began to study the local species of *Sargassum*. At first I merely familiarised myself with the

histology of the plant, then later I investigated the development of the 'Fasergrübchen,' on which subject I am disposed to come to conclusions opposed to those of Valiante in his monograph on the *Cystoceiræ*. But the greater part of the time was employed in investigating the development of the reproductive organs, and of the embryos of *Sargassum*. I was able to follow the development of the antherozoids up to the time of their discharge, which, however, I did not see. I also followed out the development of the oosphere, but did not observe the process of fertilisation. I reared and carefully observed a large number of embryos, which in their early stages much resembled those of *Cystoceira*, though many exhibited peculiarities of cell-division and growth partly due to the conditions under which they were grown. I had collected a large amount of well-preserved material, besides drawings and notes from fresh specimens, and it was my hope to have sufficient for a monograph of the Mediterranean species of the genus.

My health, however, which had been failing for some time, finally compelled me to leave Naples on August 20, 1887, four months before the end of the period granted me by the Committee. I hoped to be able to return after a short rest, but I was disappointed. Since then I have been unable to do any work, and for that reason I beg the Committee to excuse the brevity of this report.

I must express my gratitude to the Committee for the great privilege they granted me in allowing me to study at Naples, and my regret that I have been able to do so little work. I wish also to express my thanks to Dr. Dohrn and the staff of the Zoological Station for the great kindness which they showed to me, as to everyone who studies there, and for the valuable assistance they often gave me.

II. *Report on the Occupation of the Table, by Mr. ANDREW DAVID SLOAN.*

For the past year I have been deeply interested in the subject of electric organs. While assistant in the Natural History Department of Edinburgh University my attention was directed to the so-called pseudo-electric organs in the skate, and the large number of specimens obtained for dissection by the students afforded me ample material for their study. My interest in the investigation was greatly intensified by the confirmatory work of Dr. Sanderson, which supported from a physiological point of view the opinion urged by Robin after a study of its structure, viz., that the organ in the rays hitherto regarded as pseudo-electric really discharged the functions of an electric organ. I found, however, that I should be greatly aided in coming to just conclusions regarding the organ in the skates were I fully prepared for its study by a personal examination of the analogous organ of the Torpedo, which had to a much greater extent received the attention of histologists, and thus I welcomed the opportunity of effecting this purpose, which the kindness of the Committee afforded me in placing at my disposal their table in the Zoological Station at Naples.

Immediately on my arrival at the Station on March 16, everything was in readiness for me, and an abundance of living torpedoes (*T. ocellata*) at hand, and I at once began my study of the electric organ, being guided by the recent researches of Ranvier, Babuchin, Boll, Krause, &c., in the methods of treatment and observation. I was thus able to make preparations which showed me the distribution and final terminations of the

nerves, and gave me an idea of the minute structure of the electric plates. Of Wagner's 'bouquet,' a name which well denotes the appearance presented by the remarkable behaviour of the nerves before entering the plates, and of the beautiful ramifications of the branches on the plate itself, I made preparations, which, however, do no more than confirm the observations of Ranvier. The final terminations of the nerve-twigs were well brought out by the gold and silver methods, the former giving a positive and the latter a negative picture of the terminal nerve-branchings. On the disputed point as to whether the twigs from neighbouring branches communicate so as to form a network, my preparations throw some light. In many places a distinct network is visible, although very commonly the reticulation is only apparent, observation by means of a high power and more exact focussing showing a want of continuity. It is quite possible, however, that the want of continuity in these places is due to rupture of the network during the treatment or to unequal action of the stain.

The 'Punktirung' of Boll, corresponding to the 'Palisade' of Remak and the 'electric cilia' of Ranvier and Ciaccio, and of such doubtful significance, is well seen in my gold preparations, being represented by numerous violet-coloured points regularly disposed on the terminal nerve-branchings. I am sorry that I have not yet had time to make a careful examination of transverse sections of the 'electric plates,' which would reveal the little rods or 'Stäbchen' of which the 'Pünktchen' are the inferior ends. I further regret this, as I might have been able to express an opinion as to the nature of the intermediary layers of the plate, in which Krause mentions the presence of sinuous fibres.

The organ in the rays, which must now be regarded as electric, although functionally it is not of such importance as the corresponding structure in other electric fishes, would appear to be represented in all the members of the group. I have found it present in the species *Raia clavata*, *R. batis*, *R. oxyrhynchus*, *R. miraletus*, Couch (= *R. circularis*, Day), in all of which it is large and well developed, and in *R. radiata*, in which it consists of a small slender cylinder. It was first noticed in *R. clavata* by Stark (1844) and was later described by Robin in *R. clavata*, *R. rubus*, and *R. batis*, while Professor Ewart, in a series of papers read quite recently before the Royal Society, gives an account of the development of the organ in the species *R. batis*, *R. fullonica*, *R. circularis*, and *R. radiata*. The form which occurred most commonly at Naples was named *R. asterias* in the Aquarium Catalogue, and is evidently identical with our species *R. clavata*. Making use of this form, I employed my time in going over some of the ground already traversed by Robin in following out the nerve-supply and general relations of the organ. The results compared with the condition observed in the torpedo, and briefly stated, are these:—The organ is long and cylindrical in form, and tapering both anteriorly and posteriorly; it occupies a position on each side of the tail for the posterior two-thirds of its length. Its origin is in the centre of the sacro-lumbar muscle, which after the appearance of the organ gradually ceases, the electrical apparatus in like gradual manner taking its place. Indeed, embryological research shows that the electrical organ arises from a transformation of this muscle, in which the contractile substance has undergone a change. It reaches its maximum diameter about the beginning of the first dorsal fin, and after continuing of uniform thickness for several centimetres it gradually diminishes towards the tip of the tail, into which it, however, extends. In the

torpedo, on the other hand, the electric organ is somewhat flat and uniform in thickness, and occupies the entire region bounded laterally by the head and branchial sac and the margin of the body, anteriorly by the anterior boundary of the body and posteriorly by the cartilages of the pectoral fins.

In both forms the organ consists of a large number of pillars or columns, but while in the torpedo these run vertically and occupy the whole thickness of the organ, and are on the whole of a similar and uniform diameter, in the rays they run longitudinally, are of variable thickness, and have pointed extremities; nor do they extend the whole length of the organ, but after a somewhat oblique course they very soon die out. Indeed, the constituent elements of the electrical apparatus of rays are much less regularly disposed than is the case with torpedoes. The walls of the pillar consist of connective tissue, in which the nerves and blood-vessels run, and in torpedoes adjoining columns may be separated from one another, but this I have not found possible in the rays.

The columns are found to consist of a large number of superimposed plates, the electric plates, separated from each other by thin transverse partitions of connective tissue, and on one side of these the nerves ramify to a great extent and then terminate. In rays the number of plates is much less numerous than in torpedoes, the individual plates or discs are a great deal smaller in diameter, and of a much greater thickness; and, further, the ramification of the nerves takes place on the ventral face of the plate in torpedoes, while in rays it is on the anteriorly directed surface.

In the case of rays I have not been able to find any division of the nerves to supply the plates corresponding to Wagner's bouquet; they seem rather to branch in the usual way, and distribute themselves along the transverse partitions by which the columns are divided. In the torpedo the nerves run from the partition to the ventral surface of the electric plate, and there divide again and again very frequently in a perfectly dichotomous manner; this ramification takes place pretty nearly in the same plane, so that by simply placing the plate on a slide with its ventral face upwards one is able to make a study of the nerve-branchings. In rays, on the other hand, the nerves run backward from the partition immediately in front of the plate, and on their way undergo many divisions, and so reach it in the form of very delicate branches, which run perpendicularly to the surface of the disc. This can only be seen to any advantage in longitudinal or very oblique transverse sections of the organ. Before giving rise to the fine perpendicular twigs the branches of adjoining nerves anastomose, and frequently at the point of union a large nucleus is present. It is not improbable that this anastomosis may correspond to the final branching and network in the plates of the torpedo, while the fine delicate twigs may have as their homologues the 'Stäbchen' of Boll. What becomes of the nerve-fibres after they reach the plate I have not been able to make out; that they give rise to a second reticulation, and by further division become smaller and smaller and gradually pass into the substance of the plate as is stated by Schultze, I have not succeeded in confirming, and consider far from likely, the structure and development of the plate showing its elements to be muscular, and not nervous, as Schultze maintained.

The disc on which the nerves end consists anteriorly of a finely granular groundwork in which large nuclei are embedded; then follows a layer of considerable thickness characterised by the presence of

numerous long wavy lines, which according to Schultze indicates a lamellar structure, and this in turn is followed by a still thicker layer of finely granular substance containing large oval nuclei similar to that first described, but excavated and tunnelled to such an extent as to receive the name of 'Schwammkörper' from an early observer. These layers pass quite insensibly into one another, the striated appearance often occurring on the trabeculæ bounding the vacuolations, and the oval nuclei occasionally occurring amidst the sinuous lineations of the central portions. The homologue would appear to be the intermediary nucleated layer in the plate of the torpedo in which Krause describes the presence of transverse linear markings. As Robin has shown, the electrical apparatus is supplied exclusively by spinal nerves, but a point of great interest, suggested to me by Dr. Meyer, and which I hope some day to investigate, is the question as to where the fibres originate. There is strong reason to believe that they do not spring from the spinal column, but have their source in the brain.

In observing the movements of the torpedo and of the skates in the Aquarium I was struck with the difference in their modes of locomotion. The torpedo employs the tail with its powerful muscles to discharge the function of a propeller, while the skate makes use only of the pectoral fins, the tail remaining quite rigid and evidently serving to some extent as a rudder. This fact appears to me worthy of remark, and brings into prominence the importance of the organ in the skate, for it is inconceivable that a structure involving for its accommodation the transference of the entire function of locomotion to a different system of muscles should not subserve some very important function.

I frequently endeavoured to obtain a 'shock' from the skate by grasping the tails of living specimens, but although I have repeatedly made an attempt both with the smaller specimens I got at Naples and with the much larger forms which I secured when recently superintending the work of the 'Garland' for the Fishery Board for Scotland, I never succeeded in experiencing a perceptible discharge.

But besides giving attention to the structure of the electric organs in the torpedo and in the skate I devoted a considerable amount of time to the search for homologous organs among their nearest allies. This appeared to be necessary in order to throw light on the obscure problem as to how the transformation of a muscular into an electric organ could have been effected—a transformation which the researches of Babuchin, and more recently of Ewart, prove beyond a doubt. It is clear that the discovery of an imperfectly developed or of an abortive organ in any member of a neighbouring group would aid greatly in the elucidation of the question.

First of all I examined the organ in the skate, which M'Donnell described and regarded as the homologue of the electric organ in the torpedo, his work receiving a welcome recognition from Mr. Darwin; but I find it is present in a well-developed condition also in the torpedo, along with the electric organ, and exists more or less perfectly in other Elasmobranchs, e.g., in *Squatina angelus* and *Mustelus laevis*. Indeed, it is no other than the thymus gland, and its structure has no characters in common with electric organs. I studied it both in a fresh condition and by means of sections, and find it both in its intimate structure and in the nature of its contents to present a close resemblance to the thyroid, so that it evidently performs a similar function.

I further examined the tails of several other Elasmobranchs in search of an organ homologous with that of the skate, but without success. In *Torpedo ocellata*, *T. marmorata*, *Mustelus laevis*, *Scyllium canicula*, *Notidanus cinereus*, *Scymnus lichia*, the tails of which I carefully studied, I was unable to discover any trace of the structure so well developed in rays. The condition of the sacro-lumbar muscle in *Squatina angelus*, however, is worthy of remark. Its outer part is quite different in appearance from that nearest the vertebræ, being divided by connective-tissue septa into a number of longitudinal columns. The resemblance to an electric organ is, however, purely macroscopical, an examination of the more intimate structure showing no traces of change from ordinary muscle. The matter, nevertheless, is worthy of further attention, and it is interesting to note that this peculiar condition of the muscle occurs in a form which is intermediate between the round (Selachoides) and the flat (Batoidei) members of the Elasmobranch group.

Another question which I set myself to elucidate was in how far the electric organ of the skates, which varies considerably in the different species in form and size, and relation to surrounding muscles, might be made a character in determining species, but I have not yet sufficiently studied my notes to justify the expression of an opinion.

In concluding my report, I take the opportunity of expressing my deep gratitude to the Committee for their kindness in affording me such splendid facilities for prosecuting my research, and further I desire to convey my sincerest thanks to Dr. Dohrn and all the members of the staff at the Zoological Station for their unfailing courtesy and the willing help which they were always ready to render.

III. *Report on the Occupation of the Table*, by Professor R. J. ANDERSON.

I arrived in Naples on June 4. The table was furnished immediately with instruments and preserving fluids. I decided to examine the myotomes in a great number of fishes. The importance of the subject at once appears. The muscles are less complex than in other vertebrates, the primitive arrangement is largely maintained, and we have, to start with, the works of Cuvier, Meckel, Müller, and Stannius, and of Owen, Schneider and Humphry, together with the special work of Vetter, Fürbringer (whose work has some bearing on the subject), Albrecht, Goette and others. English readers are most familiar with the myological work of Humphry through his contributions to the English Journal of Anatomy and his special work on 'Myology.' The whole subject is, however, so difficult that we require abundance of facts to make any certain advance. I have, therefore, measured and noted the arrangement of the metamers in a great many fishes. I have made no reference to the embryological conditions. The general condition of things is to be found in Müller's myxinoid fishes. His description is adopted by everyone, and my work goes mainly to tease out some of the observations of that anatomist.

The fibrous partitions that separate the metamers are not planes, and the line of outcrop is a curved line. The number of the metamers, their thickness, and the number and character of the bendings all vary. The distance to which the anterior metamers reach in the cranium is not constant. I have, then, recorded—

1. The number of metamers.
2. The exact length of each segment of a number of metamers, as it appears on the surface.

3. The breadth of the metamer at the surface (lateral part).

The amount of the overlap is given in some cases. Additional facts of interest have also been given, as for instance: (a) the distinct presence of a rectus; (b) the separability of the dorsal part of the dorso-lateral muscle mass; and (c) the position of the limits with reference to the metamers. The term *rectus* is used to indicate the median ventral muscles running from the anus (each side) along each side of the median line to the pelvis, or from the pelvic to the pectoral girdle.

The actual deviation from a line on the surface formed by a transverse plane, is in many cases very considerable. The second metamer in *Sargus annularis* gives a measurement for the outcrop of its dorsal portion of 17 mm., and this runs beyond the tenth part of the entire animal. The metamer (dorsal piece) is directed from before backwards and downwards. The dorsal part of the sixth metamer reaches 24 mm. and therefore traverses one-sixth of the length of the fish. The thirteenth metamer gives 28 mm. for the first or dorsal piece. The entire length of the surface line is nearly one half the length of the animal.

Again the sixth metamer of *Gobius capito*, which has a supero-inferior diameter of 35 mm., is 57 mm. in length; the length of the fish being 187 mm., and the number of metamers, 27. The twenty-third metamer of the same fish gave a length of 52 mm. for a breadth of 20 mm. These measurements take no account of the overlap. This overlap was 24 mm. for the seventeenth metamer.

The twenty-third metamer of *Mugil cephalus* reaches 11 mm. beneath the antecedent metamers, and projects 5 mm. beneath the succeeding. In some metamers I have noted 36 mm. as the range, and this means that for an antero-posterior extent of 36 mm. an individual metamer by its zigzag windings has a situation. The seventh metamer is 92 mm. long, whilst the semi-circumference is 46 mm. The seventeenth is 72 mm. long, with a semi-circumference of 29 mm.

Trachinus Draco, one of Müller's examples, shows 12 mm. for the dorsal portion of the first, and 25 mm. for the twenty-fifth metamer. The semi-diameter is 35 mm. in the first case and 18 mm. in the second.

The dorsal part of the dorso-lateral mass is not easily distinguished as a separate mass in all fishes. In *Trigla* I was able to separate it. In *Umbrina* it can be separated for 10 metamers.

In some fishes a distinct terminal bend is to be seen in the ventral region as well as in the anterior part of the median line behind. In *Mustelus* the bends are sharp. In various fishes, in *Corvina*, for example, the dorsal curve is very distinct anteriorly. The dorsal bend is also seen well in *Belone*. In *Gobius* the ventral and lateral. The rectus is seen in *Pagellus*. Bands on each side of the anus run forwards to the pelvis. These bands correspond to the bend inwards of the myotomes, and I am inclined to think that there is some connection. The dorsal bend is well seen in *Uranoscopus scaber*.

Without giving any undue importance to the varieties in the appearances presented by the myotomes, I may state that between the condition in which there are three sharp angles anteriorly and two posteriorly superficial markings and that condition in which we have the myotome running a direct course from the median dorsal line to the median ventral, we have a great many varieties. How far the dorsal bends have a connection with the separation of the dorsal fin muscles, the dorsal, &c., I am not yet prepared to offer any opinion whatever. The bend in the lateral

line which breaks the continuity of the dorsal portion of the myotome into the ventral portion in the posterior region of some fishes is another difficulty. The full details of the observations I hope soon to complete.

IV. *A List of Papers which have been published in the year 1887 by Naturalists who have occupied Tables at the Zoological Station.*

Report of the Committee, consisting of Dr. J. H. GLADSTONE (Secretary), Professor ARMSTRONG, Mr. STEPHEN BOURNE, Miss LYDIA BECKER, Sir JOHN LUBBOCK, Bart., Dr. H. W. CROSSKEY, Sir RICHARD TEMPLE, Bart., Sir HENRY E. ROSCOE, Mr. JAMES HEYWOOD, and Professor N. STORY MASKELYNE, appointed for the purpose of continuing the inquiries relating to the teaching of Science in Elementary Schools.

WHEN your Committee made their last report in August 1887, the Government had just abandoned their Technical Instruction Bill for England, but had expressed their intention of proceeding with the Scotch Bill. The latter passed the House shortly afterwards, and provides that any School Board, after the next election, may provide and maintain Technical Schools, or that two or more School Boards may join for that purpose. A copy of the Act is given in Appendix I. A circular was issued by the Scotch Education Department in February last, calling the attention of the School Boards to the matter, and discussing the subject at considerable length. The definition of technical education given in this circular is set out in Appendix II. The Scotch Code of this year has been considerably modified in consequence of this Act; besides which it has a provision which is very interesting in its bearing on your Committee's previous recommendations. Instead of English being the subject which must be taken as the first class subject, the article now runs: 'Not more than three class subjects may be taken, and if any such subjects are taken, one must be English or Elementary Science.'

No alteration has been made in the English Code this year; and the disabilities under which the Brighton School Board and the Beethoven Street School (London) were suffering at the date of last report have not been removed.

Manual instruction has, however, been given by the London School Board, through the assistance of the City and Guilds of London Technical Institute, who have provided the sum of 1,000*l.* for one year for the equipment and maintenance of classes. A joint committee of representatives of the School Board and Institute have selected six centres, three north and three south of the Thames, and have appointed two special teachers and two artisan assistants who devote all their time to the work. In this way about 600 boys are receiving nearly three hours' instruction a week in the scientific principles and the practical work of carpentry. The School Board has asked for a further grant for a second year in consequence of no legislation having taken place this session.

The return of the Education Department for this year shows that the diminution in the teaching of the science subjects, noted in previous reports, still continues. The statistics of the class subjects for five years are given in the subjoined table, which shows an actual decrease in Geography and Elementary Science, notwithstanding the increase in the number of departments examined. The growing practice of taking needle-work in girls' schools as the second class subject (and thus obtaining for it a larger grant than would be paid for it otherwise) is gradually excluding geography.

Class Subjects.—Departments	1882-3	1883-4	1884-5	1885-6	1886-7
English	18,363	19,080	19,431	19,608	19,917
Geography	12,823	12,775	12,336	12,055	12,035
Elementary Science.	48	51	45	43	39
History	367	382	386	375	383
Drawing	—	—	—	240	505
Needlework	5,286	5,929	6,499	6,809	7,137
Total	18,524	19,137	19,263	19,522	20,099

The return of scholars individually examined in the scientific specific subjects shows again an actual falling off in the total, and either an actual or relative falling off in every subject except mechanics A and chemistry, which have both considerably increased. The figures are given in the following table:—

Specific Subjects.—Children	1882-3	1883-4	1884-5	1885-6	1886-7
Algebra	26,547	24,787	25,347	25,393	25,103
Euclid and Mensuration	1,942	2,010	1,269	1,247	995
Mechanics A	2,042	3,174	3,527	4,844	6,315
„ B	—	206	239	128	33
Animal Physiology	22,759	22,857	20,869	18,523	17,338
Botany	3,280	2,604	2,415	1,992	1,589
Principles of Agriculture	1,357	1,859	1,481	1,351	1,137
Chemistry	1,132	1,047	1,095	1,158	1,488
Sound, Light and Heat	630	1,253	1,231	1,334	1,158
Magnetism and Electricity	3,643	3,244	2,864	2,951	2,250
Domestic Economy	19,582	21,458	19,437	19,556	20,716
Total.	82,965	84,499	79,774	78,477	78,122
Number of Scholars in Standards V., VI., and VII.	286,355	325,205	352,860	393,289	432,097

The rapid and serious decrease of attention paid to these science subjects is shown by the percentage of children who have taken them, as compared with the number of scholars that might have taken these subjects, viz. :—

In 1882-3	29·0 per cent.
„ 1883-4	26·0 „
„ 1884-5	22·6 „
„ 1885-6	19·9 „
„ 1886-7	18·1 „

and it must be remembered that children who have taken two of these subjects count twice over.

The Special Committee of the London School Board ‘on the subjects and modes of instruction in the Board’s schools,’ which was referred to on the last occasion, has presented its report. The report itself, prepared by Mr. W. Bousfield, which is a lengthy and important document, is strongly in favour of much greater attention being paid to science. The

appendix contains valuable evidence from several scientific men, amongst others; and statistical tables relating to the instruction now given in the schools under the Board. From these it appears that object lessons are given in all the infant schools, occupying on an average about one and a half hours per week, and in 91 per cent. of the boys' and girls' schools; but in the case of many of these they are confined to the lower standards, and the average time devoted to them is less than three-quarters of an hour per week. This is in strange contrast with the ten and a quarter hours per week, which is the average quantity given in the boys' schools, and nine and a quarter in the girls' schools, to the literary subjects of instruction—reading, writing, spelling, and grammar—and to the four hours at least per week which the girls are expected to give to needle-work. Though these object lessons are the principal means by which a knowledge of science is given, about half of the elder boys get some instruction in some scientific specific subjects. The principal recommendations in which your Committee are interested are:—

1. That the methods of Kindergarten teaching in infants' schools be developed for senior scholars throughout the standards in schools, so as to supply a graduated course of manual training in connection with science teaching and object lessons.

2. That the teaching of all subjects be accompanied, where possible, by experiments and ocular demonstration, and that the necessary apparatus be supplied to the schools.

10. That greater attention be paid to the teaching of mechanics as a specific subject, and that models for illustrating the instruction be placed on the requisition list.

16. That, in order to allow time for experimental teaching and manual work, the time now given to spelling, parsing, and grammar generally, be reduced.

28. That application be made to the Education Department that the new Code be revised, as follows:—

(b.) By applying to senior departments the regulation made with regard to infants' departments in Article 106 (b.) of the new Code, viz., that the award of a merit grant should have 'regard to the provision made for . . . simple lessons on objects, and on the phenomena of nature and of common life.'

(c.) By providing that more freedom of choice may be given to managers and teachers in the selection of class subjects, in order that the first class subject need not necessarily be English.

(f.) By rendering it obligatory upon pupil-teachers to exhibit a knowledge of elementary science in some form at their annual examinations. (Schedule V.)

A lengthy discussion on the general principles of the Report has taken place, and the first recommendation has been carried, with the addition of the words, 'but not so as to include teaching the practice of any trade or industry, and that the method of Kindergarten in the senior schools be tried first in a few special schools throughout London.'

Two Technical Instruction Bills have been brought into Parliament again this year—the one by Sir Henry E. Roscoe and the other by the Government—but each of them considerably varied from those of the preceding year. Neither of them progressed beyond the first reading; the former having been supplanted by the Bill of the Government, which,

however, met with little approval, and was withdrawn in July along with several others.

The reason generally given why legislative and executive changes have not been made during the year is that the Government is waiting for the Report of the Royal Commission on the working of the Elementary Education Acts of England and Wales. Since the Manchester meeting the Royal Commission have published another volume of evidence, and an analysis of the whole; but they have not yet finally settled their recommendations.

In the meantime public opinion has considerably ripened upon the subject of scientific and practical education. This is evident by the earnest manner in which it is now discussed by politicians and teachers, and in the columns of the periodical press.

APPENDIX I.

Technical Schools (Scotland) Act, 1887.

Be it enacted by the Queen's Most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows :

I. This Act may be cited as the Technical Schools (Scotland) Act, 1887, and shall in so far as consistent with the tenor thereof be construed as one with the Education (Scotland) Acts, 1872 to 1883.

II. This Act shall commence to have effect in each parish and burgh in Scotland from and after the next ensuing triennial election of a school board therein respectively, and shall apply to Scotland only.

III. (1.) A school board may pass a resolution that it is expedient to provide a technical school for its district, and thereupon may, subject to the provisions of this Act, provide such a school accordingly, and pay the expenses of providing and maintaining the school, including the expense, if any, of providing tools, apparatus, and drawing and other materials, in so far as the same remain the property of the school board, out of the school fund. The subjects to be taught in the school shall be such as may from time to time be approved of by the Scotch Education Department.

The school board shall fix the school fees to be paid for attendance at each technical school under their management, and such fees shall be paid to the treasurer of the board, and a separate account shall be kept of the amount of the fees derived from such school, and it shall be lawful for the school board, if they see fit, to pay to the teachers of a technical school the fees derived from such school, and to divide the same among them as the school board shall determine. Any deficiency which may exist on the technical school account shall be payable out of the school fund provided under the Education (Scotland) Acts, 1872 to 1883.

(2.) If the resolution is not confirmed as hereinafter mentioned, it shall not be carried into effect, and shall not be again proposed until the expiration of not less than twelve months.

IV. A resolution of a school board, as in the last section mentioned, shall be of no effect unless and until—

(1.) It is confirmed at a subsequent meeting of the school board held after the resolution has been published in the prescribed manner, and

after the expiration of the prescribed time, being not earlier than one month after the first publication of such resolution ; and

(2.) It is confirmed by the Scotch Education Department by a Minute or Order.

V. (1.) Every school provided under this Act if it claim a grant from the Department of Science and Art shall, with respect to any subject for which such grant is claimed, be conducted in accordance with the conditions specified in the Minutes of the Department of Science and Art in force for the time being, and required to be fulfilled by such a school in order to obtain a grant from that Department.

(2.) Those conditions shall, amongst other things, provide that a grant shall not be made by the Department of Science and Art in respect of a scholar admitted to the school unless or until he has obtained such a certificate from the Scotch Education Department as is hereinafter mentioned.

(3.) A Minute of the Department of Science and Art not in force at the passing of this Act shall not be deemed to be in force for the purposes of this Act until it has lain for not less than one month during one session on the Table of both Houses of Parliament.

VI. Every school provided under this Act shall, in respect to all subjects other than those for which a grant is claimed from the Science and Art Department, be conducted in accordance with the conditions which may from time to time be set forth in the Scotch Education Code annually laid before Parliament under the heading 'Technical Schools.'

VII. (1.) Every school board providing a technical school shall, subject to the provisions of this Act, maintain and keep efficient the school so provided.

(2.) For the purpose of providing any such school, a school board shall have the same powers, but subject to the same conditions, as a school board has for providing sufficient school accommodation for its district.

(3.) For the purpose of maintaining any such school, a school board shall have the same powers, but subject to the same conditions, as a school board has in regard to the maintenance of a higher class public school under section eighteen of the Education (Scotland) Act, 1878.

(4.) A school board may, with the consent of the Scotch Education Department, use for the purposes of a technical school any buildings, or part of any buildings, vested therein for the purposes of the Education (Scotland) Acts, 1872 to 1883, and a school board, or combination of school boards, may, with the consent of the Scotch Education Department, use for the purposes of the Education (Scotland) Acts, 1872 to 1883, any buildings, or part of any buildings, authorised by this Act.

(5.) A school board may, with the consent of the Scotch Education Department, spread the payment of the expense of providing a technical school over a number of years, not exceeding thirty-five years, unless with the sanction of the Treasury, and in any case not exceeding fifty, and may borrow money for that purpose ; and for the purpose of such borrowing section forty-five of the Education (Scotland) Act, 1872, shall be held to apply to the loan, and such provision shall be deemed to be a work for which a school board is authorised to borrow, and the Public Works Loan Commissioners are authorised to lend, within the meaning of the ninth section and the First Schedule of the Public Works Loans Act, 1875.

(6.) Where a school board has provided any such school, it may discontinue the school, or change the site thereof, if it satisfies the Scotch Education Department that the school to be discontinued is unnecessary, or that the change of site is expedient.

VIII. Any two or more school boards may resolve to combine together for the purpose of providing and maintaining a technical school under this Act common to the districts of such school boards, provided that no such resolution shall have any effect unless and until it has been published and confirmed in manner hereinbefore provided; and if such resolution is confirmed as aforesaid, the same provisions shall have effect as in the case of a resolution to provide a technical school, and if the resolution is carried into effect the expenses of providing or maintaining the school, and the sum necessary to meet any deficiency on the technical school account, shall be paid out of the school funds of the combining school boards in terms of the said resolution.

IX. The provisions of sections thirty-eight and thirty-nine of the Education (Scotland) Act, 1872, with respect to the transference of schools in pursuance of those sections, shall apply to technical schools now existing, or which may hereafter exist, in the same manner as they now apply to the schools which may presently be transferred in pursuance of those sections.

X. No scholar shall be admitted to a technical school unless or until he has obtained a certificate under section seventy-three of the Education (Scotland) Act, 1872, as amended by section seven of the Education (Scotland) Act, 1883, or an examination equivalent thereto.

XI. A technical school provided and maintained under this Act shall be deemed to be a public school, but attendance thereat shall not be reckoned as attendance for the purpose of any grant from moneys voted by Parliament under the Education (Scotland) Acts, 1872 to 1883.

XII. In this Act—

The expression 'technical school' means a school or department of a school in which technical instruction is given, and school board shall include combination of school boards.

The expression 'technical instruction' means instruction in subjects approved by the Scotch Education Department, and in the branches of science and art with respect to which grants are for the time being made by the Department of Science and Art, or in any other subject which may for the time being be sanctioned by that Department.

The expression 'prescribed' means prescribed by the Scotch Education Department.

APPENDIX II.

'However desirable it might be, it is scarcely possible to frame a definition of technical education which can be satisfactory from all points of view; but without any such comprehensive definition it may be possible to lay down certain outlines of the operations permissible under the Act. Their lordships assume that such instruction may be held to cover not only the general scientific principles which underlie the leading manufactures and industries of the kingdom, but also some knowledge of the manner in which these general principles are applied, and some acquaintance with the practical conditions under which they are applied in various industries, and in various localities. Besides this general description, they apprehend that the ordinary interpretation of the term covers some

practical training of hand and eye, some adapting of the ordinary lessons of the school to the affairs of life, and to the acquiring of aptitude in the special occupation in which the scholar is to be engaged.'

POSTSCRIPT.

Since the foregoing report was prepared Mr. Samuel Smith's Continuation Schools Bill has been printed, and the final report of the Royal Commission on the Working of the Elementary Education Acts, England and Wales, has been issued.

The former provides that in the Continuation schools proposed to be created instruction must be given in at least three of the subjects specified in the First Schedule, which includes, *inter alia*, elementary mathematics, mechanical drawing, and elements of agricultural science, and may be given in any of the subjects specified in the Second Schedule, which includes use of tools, and art handwork generally.

The final report of the Royal Commission is a very lengthy document, and contains a large amount of matter bearing upon the subject with which your Committee have to deal. The following are some of the principal recommendations affecting the teaching of science in elementary schools :—

'(15.) That in making future appointments to the office of inspector, it would be desirable, in regard to a larger proportion of them than at present, to give special weight to the possession of an adequate knowledge of natural science.

'(89.) That, as far as practicable, the children should be grounded in all the four class subjects, and that when only some of them are taken the selection should be left to the school authorities.

'(90.) That the provision of the Code, which requires that if only one class subject is taken it must be "English," should be repealed.

'(93.) That geography, if properly taught, is a branch of elementary science, which should not be separated from the other branches, and might well be taught along with object lessons, in accordance with the recommendations of the Royal Commission on Technical Instruction.

'(94.) That in Standard VII. the time allotted to geography might advantageously be devoted to specialising some particular branch of the subject.

'(114.) That the following subjects of elementary instruction are to be regarded as essential, subject to the qualifications we have already made :—

Geography, especially of the British Empire.

Lessons on common objects in the lower standards, leading up to a knowledge of elementary science in the higher standards.

'(118.) That though boys while at school should not be taught a trade, some elementary instruction in science is only second in importance to the three elementary subjects.

'(120.) That the curriculum of elementary scientific subjects might vary according to the special requirements of each locality.

'(121.) That object lessons should be continued in the lower standards in succession to similar teaching in the infant school.

'(123.) That the curriculum in the ordinary elementary schools might often include not only instruction in the elementary principles of science,

but also, in certain standards, elementary manual instruction in the use of tools; and in higher schools and evening schools this work might be carried still further.

‘(124.) That if technical instruction of this kind is to be given in our schools, it should not be applicable to boys under ten years of age. The ultimate object of such instruction, however, might be furthered by judicious systematical science teaching given to the younger scholars, in which they should be associated in preparing specimens, helping to make models on their geography lessons, and so forth.

‘(125.) That examinations in science should as far as possible be conducted orally and not on paper, especially in the first five standards.

‘(126.) That if it should be thought that children ought to receive some instruction in manual employment other than that which the elementary schools available for their use can give, the best way of meeting the need would be by the establishment in connection with some higher institution of a workshop for boys of exceptional ability, or for others to whom it was considered desirable to give this instruction.

‘(127.) That arrangements might be made to substitute attendance at such a centre on one or two afternoons in the week for attendance at the elementary school.

‘(128.) That the higher grades of elementary schools in which more advanced science is taught, and where a certain number of children stay beyond the seventh standard, may be regarded as continuation schools.

‘(136.) That it is desirable that the management of technical instruction should be entrusted to the Education Department, and not to the Science and Art Department.

‘(142.) That the evening school system should be thoroughly revised; that a special curriculum and special schedules of standards and subjects should be allowed, suitable to the needs of a locality, and that the local managers should be encouraged to submit such schedules to the Department for approval; that the provision embodied in the Code requiring all scholars in evening schools to pass in the three elementary subjects as a condition of taking of additional subjects should cease to be enforced; and that no superior limit of age should be imposed on the scholars.

‘(151.) That a knowledge of the principles of agriculture, which might be taught in higher elementary schools, where such existed in country places, would be of great value to those children who might hereafter be engaged in agricultural labour.

‘(152.) That in certain cases the object of higher elementary schools might be secured by attaching to an ordinary elementary school a class or section in which higher instruction was provided for scholars who had passed the seventh standard. That liberal grants made, as in Scotland, to the managers of elementary schools for advanced instruction to scholars who have passed the highest standard, would facilitate the provision of such higher instruction in the smaller and less populous school districts.’

These recommendations were signed by fifteen out of the twenty-three Commissioners. The remaining eight presented an entirely separate report, as they differed from their colleagues on many other points; but they agree in principle with the above recommendations so far as your Committee have quoted them. The following are some of the comments of the minority, which will show that they are at least equally desirous of seeing greater facilities given for instruction in science in elementary schools.

‘We agree that the present special preference of English above the other class subjects should be removed from the Code.

‘We agree that higher elementary schools are a useful (we would rather say a necessary) addition to our school machinery for primary education. . . . That where such schools cannot be founded, higher classes for children who have passed the seventh standard should be attached to an ordinary elementary school.

‘We dissent from the recommendations of our colleagues as to the management of technical schools when established. . . . We would say . . . that these schools, which should be the crown and development of elementary education, should be in touch and close sympathy through their management with our elementary school system.

‘In reference to the subject of technical and scientific instruction, we draw an important distinction between technical instruction or instruction which is designed with special reference to, and as a preliminary training for, the commercial or industrial occupations of life, and manual instruction regarded as a training of the hand and eye so as to bring them under the control of the brain and will, as a general preparation for the future career in life, whatever it may be.

‘Bearing in mind the age of children in elementary schools, it may be a question whether technical instruction, as we have defined it, should be commenced any earlier than the sixth standard. But we are of opinion that, after the children have left the infant school, transitional methods should be adopted, which will develop their activity and train their powers by drawing in all cases, and by such other means as, for instance, modelling, or the collection and mounting of botanical specimens.

‘This training would, on the one hand, be advantageous as naturally leading up to technical instruction, and, on the other hand, far from interfering with the more literary studies, the latter would, we believe, benefit considerably by the variety and relief which would thus be introduced.

‘We recommend that the examination of the scientific teaching given in our elementary schools should be mainly oral, especially up to and including the present fifth standard. If science is to be well taught, care should be taken that where the ordinary teachers are not qualified, specially trained teachers should be employed.

‘Higher grade schools should be encouraged which will prepare scholars for advanced technical and commercial instruction.

‘Technical teaching in the school cannot replace the practical teaching, which is best learnt in the workshop.

‘In ordinary elementary schools good teaching of drawing and of elementary science are the best, and in the lower classes the only fitting preparation for the work of the technical school, and these subjects should be generally taught.

‘Technical instruction should cover commercial and agricultural as well as industrial instruction.’

Sixth Report of the Committee, consisting of Mr. R. ETHERIDGE, Dr. H. WOODWARD, and Professor T. RUPERT JONES (Secretary). on the Fossil Phyllopoda of the Palæozoic Rocks.

§ I. *Monograph*.—‘A Monograph of the British Palæozoic *Phyllopoda* (*Phyllocarida*, Packard), Part I., *Ceratiocaridæ*,’ based on our former Reports to the British Association for the Advancement of Science, was published in January of this year by the Palæontographical Society. The genera and species treated of are those enumerated in the table at page 234 of the Report for 1886, excepting that *Ceratiocaris attenuata* was found to be Salter's *C. tyrannus*; to this species also may be referred pl. 2, fig. 4, pl. 4, fig. 3, pl. 5, fig. 6, and pl. 6, fig. 11 of the Monograph. the style or telson being strong and straight (not curved as in its nearly, *C. Murchisoni*). The Portuguese fossil *Phyllocarid*, first named and described by D. Sharpe as *Dithyrocaris* (?) *longicaula* (?) is also included, with illustrations (being within reach at the Geological Society of London), as a doubtful *Ceratiocaris*.

§ II. *Ceratiocaris tyrannus*.—Professor Sven Leonhard Törnquist, of Lund, has sent to us for examination some fragments of the caudal appendage of a *Ceratiocaris* from the Upper Coldwell Beds, near Troutbeck, Westmoreland. The specimen consists of a style and two stylets, imperfect at the ends, in a sandy mudstone. One stylet lies close to the style, and the other is indicated by a cast at an angle with its fellow. They are all straight and the style shows a lateral row of pits (bases of spinules). It is too straight for *C. Murchisoni*, and the pits are too small for *C. gigas*. It may belong to *C. tyrannus*, like the specimen (also from Westmoreland), referred to *C. valida*, perhaps wrongly, ‘Monogr. Foss. Phyll.’ p. 21, pl. 6, f. 11. The specimen shown by pl. 4, fig. 3, is also probably *C. tyrannus* and not *C. Murchisoni*.

§ III. *Ceratiocaridæ from Sweden*.—The Scandinavian *Phyllocarida* mentioned in the last ‘Report’ (Manchester meeting, 1887), pp. 60–62, have been fully described and figured in the ‘Geological Magazine’ for March 1888, pp. 97–100, pl. 5, and for April, pp. 145–150, pl. 6 and woodcuts. *Ceratiocaris valida* has been added with some probability as occurring in Sweden. In *C. Angelini* the style (telson) was probably only 7 (not 15) mm. longer than in pl. 5, fig. 1, p. 97; and the row of little pits (bases of prickles) is on the right-hand (not left-hand) side of the cast as figured, *ibid.*, see also *ibid.*, p. 150.

With this revised and enlarged description of the Phyllocaridal remains from Sweden are associated descriptions and figures of both Scandinavian and British specimens of the masticatory organs ('teeth') of *Ceratiocaris*.

We ought to have added that Mr. T. P. Barkas has given two rough figures of a similar tooth, belonging probably to *Dithyrocaris*,¹ in his 'Manual of Coal-measure Palæontology,' or 'Illustrated Guide to the Fish, Amphibian, Reptilian, and supposed Mammalian Remains of the Northumberland Carboniferous Strata,' 8vo, and 'Atlas of Carboniferous Fossils from the Northumberland Carboniferous Strata,' fol., 1873. These enlarged views of a Crustacean tooth are figs. 161 and 162 in pl. 5, and the specimen is described as the *Anthropodontoides Baileii*, at p. 45.

§ IV. *Bohemian Phyllocarida, &c.*—M. Ottomar Novák has further enlarged our knowledge of the Palæozoic Phyllopodous Crustaceans during his critical examination of the 'Barrande Collection,' of which he has the charge in the Prague Museum.

In the Stage F-f1, of the Hercynian Formation, he finds an undescribed telson, relatively short and stout, 39 mm. in length, swollen for about 10 mm. from the top, afterwards neatly ridged and fluted dorsally, and bearing a row of small pits along each outer ridge. This he defines as *Aristozoe solitaria*, at p. 15, pl. 1, figs. 15-19, of his 'Zur Kenntniss der Fauna der Etage F-f1 in der paläozoischen Schichtengruppe Böhmens'; 'Sitzungsber. k. böhm. Gesell. Wissensch.,' Jahrgang 1886. At p. 15 M. Novák explains that *Aristozoe* had only one caudal spine, namely, the telson or style. In the Table at p. 17 he mentions two new species of *Ceratiocaris* (not described, *C. modesta* and *C. Damesi*) from the same Stage.

In our Second Report (for 1884), at p. 87, we offered the remark that most of Barrande's species of *Cryptocaris* and *Zonozoe* were probably opercula of some Shells, or possibly of some Corals such as *Goniophyllum*. M. Novák finds evidence that some at least of the *Cryptocarides* are referable to the Conularian *Orthotheca* or *Hyolithes*, and that *Cryptocaris suavis*, Barrande, in particular, is the operculum of *Orthotheca* (*Hyolithes*) *intermedia*, Novák. 'Sitzungsb. böhm. Ges. Wiss.' 1886, pp. 7-14, pl. 1, figs. 9-13.

We may add that in his 'Illustrations of the Fauna of the St.-John Group, No. III.,' in the 'Transact. Roy. Soc. Canada,' Section IV., 1885, Mr. G. F. Matthew has described and figured some fossil Pteropoda (*Hyolithes*, &c.), together with their opercula (p. 48, &c., pl. 6, figs. 1, 2, 5, 6, 7). These latter are evidently the same as Barrande's *Cryptocaris*. Other probable opercula are figured and described in the same work (pp. 61-66, pl. 6, figs. 16-21), under the generic names of *Lepiditta*, *Lepidilla*, *Hipponicharion*, and *Beyrichona*; some being regarded as Ostracods, and others doubtfully as Phyllopods.

§ V. *Ptychocaris* (?) *Jaschei*.—M. Ottomar Novák has favoured us with the following note:—

'*Dithyrocaris Jaschei*, figured by Kayser in the "Abhandl.," &c., pl. 1, fig. 13, and mentioned in the Fifth Report on the Fossil Phyllopoda of the Palæozoic Rocks, p. 66, shows some resemblance to my *Ptychocaris*

¹ Similar to those described and figured in the *Geol. Mag.*, 1865, p. 401, pl. 11, fig. 8; and 1873, p. 486, pl. 16, fig. 2g.

(see Fourth Report, &c., p. 233), which occurs at an equivalent horizon—the “Hercynian” of Beyrich and Kayser, = “Etages F, G, and H,” of Barrande.’

§ VI. *Devonian Phyllocarida of New-York State*.—In the ‘Bulletin of the U. S. Geological Survey,’ No. 16, 8vo, 1885, Mr. John M. Clarke has given a memoir ‘On the Higher Devonian Faunas of Ontario County, New York,’ in which he describes and figures the following Phyllocarida:—

1. *Ceratiocaris simplex*, J. M. C., p. 43 (77), pl. 2, fig. 2. Carapace-valve nearly oval in outline, 30 mm. long and about 10 mm. wide (high).

2. *C. Beecheri*, J. M. C., p. 44 (78), pl. 2, fig. 1. Three abdominal segments and three caudal spines, not well preserved. Proportionally too large for the foregoing species. The ultimate segment is apparently shorter than usual in this genus.

3. *Echinocaris Whitfieldi*, J. M. C., p. 45 (79), pl. 2, figs. 3 and 4. Carapace-valve 27 mm. long and 16 mm. wide (high); with the middle and one of the lateral caudal spines, the latter longer than the former.

4. *Equisetides Wrightiana*, Dawson, 1881 (*Echinocaris Wrightiana*, J. & W. ‘Geol. Mag.,’ 1884, p. 395, pl. 13, fig. 1), is mentioned at p. 66 (100). See also our Third Report (for 1885), p. 360.

5. *Spathiocaris Emersoni*, J. M. C. Notes on the genus and localities for this species are given at pp. 46 (80) and 47 (81).

In the Table at p. 69 (103) *Ceratiocaris longicauda*, Hall, is noted as occurring in the ‘Genessee Shales’ and the ‘Portage Beds,’ in which latter occur also *Dipterocaris pennæ-Dædali*, Cl., *D. pes-cervæ*, Cl., and *D. Procne*, Cl. The ‘Naples Shales’ have yielded *Ceratiocaris simplex*, Cl., *C. Beecheri*, Cl., *Echinocaris Whitfieldi*, Cl., *Ech. Wrightiana* (Dawson), and *Spathiocaris Emersoni*, Cl. See also our Second Report (for 1884), pp. 78, 80, 81.

§ VII. *Bactropus in Devonshire*.—The Rev. G. F. Whidborne, F.G.S., has identified from the Devonian strata of Torquay a specimen of *Bactropus longipes*(?), Barrande, which M. Ottomar Novák¹ has shown to be really the chief abdominal segment (or ‘post-abdomen’) of Barrande’s *Aristozoe regina*; whilst *Ceratiocaris debilis*, Barrande, is the style (telson) of the same bivalved Crustacean (Phyllocarid).

§ VIII. *Tremadoc Fossils*.—In the First Report on the Palæozoic Phyllopoda (1883) a tabular synopsis of the known fossil genera was published, together with descriptive notes on some of the species, from the Tremadoc and other old rocks, including *Hymenocaris*, *Caryocaris*, and *Lingulocaris*. The well-known *Hymenocaris vermicauda* is therein described from specimens obtained from many localities of the Lingula-flag and Tremadoc-slate series of North Wales, and preserved in the collections of the British Museum, Geological Survey, Cambridge University, and Owens College. The track-marks on Lingula-flags, near Tremadoc, ascribed by Salter to *Hymenocaris*, are also alluded to.

The ‘*Hymenocaris (Saccocaris) major*’ of Salter is also referred to at pp. 219, 220. Though three specimens have been thus labelled in the Cambridge Museum, with some doubt and possibly by Salter himself, only one of them answers to Salter’s brief generic description, and on this the following determination is founded.

¹ *Sitzungsber. k. böhm. Gesell. Wissensch.*, Jahrgang 1885, pp. 239–243, pl. 1. See also our Report for 1885, p. 359.

1. SACCOCARIS MAJOR, Salter. (Woodcut, Fig. 1.)

Saccocaris, Salter, 1868. 'Report Proc. Geol. Polytech. Soc. West. Riding of Yorkshire' (for 1867), vol. iv. 1868, p. 588.

Hymenocaris (*Saccocaris*) *major*, Salter, 1873. 'Catal. Palæoz. Fossils, Cambridge Museum,' p. 7. Referring to 'Halifax Trans.' 1867,' by mistake.

The particular specimen which most nearly corresponds with the original description, namely, 'a large ovate carapace, strongly emarginate behind, and larger than *H. vermicauda*,' is a relatively large, thin, filmy, compressed valve, $4\frac{2}{16}$ inches long and 2 inches high,¹ suboblong, with nearly parallel dorsal and ventral borders, the former straighter than the latter, which has a slight outward (downward) curve. Obliquely elliptical in front, the acme of the curvature being above the mesial line, thus making the antero-dorsal much shorter than the antero-ventral curve. Apparently blunt or truncate behind, with a gentle outward curve rather above the middle. The exact line of this posterior margin is not clearly seen, owing to its being shredded or frayed off, thus passing into the substance of the black schistose mudstone; the valve having been delicately plaited (with the stone) by lateral pressure acting at right angles to its length, and this longitudinal plaiting being transverse to the hind border. The front edge has not been affected nearly so much, having probably been thicker, or even slightly rimmed. This pressure has, perhaps, somewhat elongated the valve, and lessened its original height, besides giving it a gentle undulation, as well as the plaiting (pleating), throughout.

The valve, slightly hollow, is probably the right-hand valve, showing its inside. Several concentric, irregular, narrow foldings, following the contour of the anterior and antero-ventral border, are apparently due to the compression of the convexity of the valve.

This specimen, No. 1, at p. 220 of the First Report, and fig. 1 of the accompanying woodcuts, is marked $\frac{1}{160}$, $\frac{b}{257}$, in the Woodwardian Museum of the Cambridge University, and was collected by Mr. D. Homfray from the upper part of the Lower Lingula-flags at Caer-y-coed, near Maentwrog.

This was at first (in 1867) regarded by Mr. Salter as a flat carapace, 'after the manner of *Apus*'; but afterwards (in 1873) he referred it to the bivalved, folded, or Nebalioid forms of carapace, and placed it as an ally of *Hymenocaris*, with the name *Saccocaris*. In shape it differs much from the valves of that genus, as it wants their triangular form, due to the dorsal line forming an angle with the front edge, which slopes rapidly downwards and backwards all along the ventral, to join the posterior margin with a bold, oblique, postero-ventral curve. Differing also remarkably in size, it must be assigned to a different generic group; and it will be best to recall the name Salter was at first inclined to give it, namely, SACCOCARIS.

2. LINGULOCARIS SALTERIANA, sp. nov. (Woodcuts, Figs. 6 & 7.)

The British Museum has lately acquired a fine specimen of one of the old Cambrian Phyllocarids, from the Tremadoc-slate series. It is a black,

¹ *H. vermicauda* rarely attained more than an inch in length along the back, 8 or 9 tenths of an inch in height, and one and 3 or 4 tenths of an inch in the greatest angular length from antero-dorsal to postero-ventral region

shining, and filmy valve (or compressed bivalved carapace), seen as an impression and counterpart on a split slab of hard, grey, micaceous mudstone, which has been subjected to the usual lateral pressure. The valve ($3\frac{1}{4}$? \times $1\frac{1}{8}$ inch) is acutely subovate, or sharply boat-shaped in outline, convex below and straight above, and was acute probably at each end, though one of them is damaged. It retains a remnant of one of the small, subtriangular, terminal extensions of the dorsal edge, such as are present in *L. siliquiformis*. See fig. 6 of the annexed woodcuts.

The surface is peculiarly marked with what seem to be modifications of ornamental striæ or linear plaits, namely, very small lenticular and bead-like elevations, which may have resulted from raised longitudinal striæ being crossed by the delicate plaiting of lateral pressure at slightly different angles.

We dedicate this fine species to the memory of our friend, Mr. J. W. Salter, whose labours in elucidating these old Phyllopodous forms are well known. It was found by Dr. R. Roberts in the Tuhwntirbwlich quarry at Portmadoc.

Another of the old associates of *Hymenocaris* in the Tremadoc series is the 'second specimen' mentioned at p. 220 of our First Report (1883). Though smaller than the foregoing ($2\frac{5}{8} \times 1\frac{3}{8}$ inch), it is of a similar shape, having been acute at both ends (probably, though one is broken), elliptically curved below and nearly straight above, thus having the outline of a sharp-ended boat (fig. 7 of the annexed woodcuts). It is not really 'emarginate' at one end, as stated at p. 220 of the Report, that appearance being due to a slight transverse crack and some inequality of the surface near the end, which was probably acute, but has been squeezed out of shape and frayed away by the longitudinal plaiting of the hard, compressed, slaty shale or mudstone. The cross-pressure has also coarsely plaited the valve throughout, and somewhat lengthened it.

From the upper part of the Lower Lingula-flags, at Caer-y-coed, near Maentwrog. Collected by Mr. D. Homfray. In the Woodwardian Museum, Cambridge.

A somewhat similar, but badly preserved, fossil from the Brethay Flags of Long Sleddale (Marr Coll. in the Cambridge Museum) is probably a *Lingulocaris* of the same, or a closely allied, species.

3. LINGULOCARIS SILIQUIFORMIS, J. and W. (Woodcuts, Figs. 8 & 9.) 'Geol. Mag.,' 1883, p. 464.

At p. 223 of the First Report (1883) we described this Cambrian Phyllocarid as differing from Salter's *L. lingulæcomes*¹ by being longer, sharper at one end, and more nearly resembling a pea-pod in shape. One specimen (fig. 8 of the annexed woodcuts), rather wrinkled by crush, from the Upper Tremadoc series at Garth Hill, Portmadoc, was presented to the British Museum by the Rev. J. F. Blake. Another (fig. 9), also in the British Museum, is marked '48654 from the Bala Schist at Bwlch-y-gaseg, near Cynwyn, Corwen; J.P., March 14, 1868.'

A fragmental specimen from the Upper Tremadoc series at Garth, Portmadoc, is in the Museum of Practical Geology, marked $\frac{2}{4}$; and referred to *L. lingulæcomes* at p. 15, 'Catal. Cambr. and Silur. Foss. M. P. G.,' 1878.

¹ Besides the two specimens, ^A₃₇₃ in the Woodwardian Museum (see First Report p. 223), from Garth, there is one in the British Museum, No. 48,001, from the same locality.

4. CERATIOCARIS (?), sp. Fig. 10, of the Woodcuts.

A posterior portion of a valve like that of *Ceratiocaris* was described at p. 220 of the First Report (1883). It is $\frac{2}{10} \times \frac{1}{2}$ inch in measurement; from Wern, near Portmadoc; and marked $\frac{A}{170}$ in the Woodwardian Museum, Cambridge.

The body-pieces known as Salter's *Ceratiocaris* (?) *lata*, from Garth, and *C.* (?) *insperata*, from Penmorfa (see our First Report, p. 221, and Third Report, 1885, p. 351), appear to be too large for this species from Wern.

5. HYMENOCARIS. (Woodcuts, Figs. 2-5.)

In illustration of *Hymenocaris vermicauda*, Salter, outline sketches of some of the best known specimens are given in figs. 2-5 of the accompanying woodcuts. The modified shapes of the valves, and of the body-rings variable in number, are here indicated to illustrate the descriptions in the First Report, pp. 218, 219; and to serve for comparison with their associates *Saccocaris*, *Lingulocaris*, and *Ceratiocaris* (?), above described (figs. 1, 6-10).

Explanation of the Figures (Woodcuts). Natural size.

- FIG. 1. *Saccocaris major*, Salter. Caer-y-coed, near Maentwrog; upper part of the Lower Lingula-flags.
- FIG. 2. *Hymenocaris vermicauda*, Salter. Carapace much narrowed by transverse pressure. Borth, Portmadoc; Ffestiniog group.
- FIG. 3. ——— Carapace and abdomen modified by pressure. Borth.
- FIG. 4. ——— Carapace and abdomen the former somewhat shortened and widened by pressure, but nearly of the original shape. Borth.
- FIG. 5. ——— Carapace and abdomen modified by pressure. Borth.
- FIG. 6. *Lingulocaris Salteriana*, sp. nov. Flattened carapace; damaged at the ends. Tuhwtirbwlch quarry, Portmadoc.
- FIG. 7. ——— (?). Smaller individual. Carapace flattened, and somewhat narrowed and lengthened by transverse pressure. Caer-y-coed, near Maentwrog; Lower Lingula-flags.
- FIG. 8. ——— *siliquiformis*, J. & W. Garth Hill, Tremadoc; Upper Tremadoc series.
- FIG. 9. ——— Bwlch-y-gaseg, near Cynwyd, Corwen; Bala-schist.
- FIG. 10. *Ceratiocaris* (?), sp. Hinder moiety of valve. Portmadoc; Ffestiniog group.

§ IX. *Estheria*.—Some specimens of *Estheria membranacea* (Pacht), in a black limestone, including the long variety (p. 15: 'Monogr. Foss. Estheriæ,' 1863), collected lately by Mr. Jex, in Orkney, have been placed in the British Museum.

§ X. *Devonian Phyllocarids of New-York State, &c.*—The following genera and species are fully noticed and carefully figured in Prof. Dr. James Hall's last volume of the 'Palæontology of the State of New York,' just lately published. They are of Devonian age, and with few exceptions from the district mentioned. The title of this important volume is 'Geological Survey of the State of New York. Palæontology: Vol. VII. Text and plates. Containing descriptions of the Trilobites and other Crustacea of the Oriskany, Upper Helderberg, Hamilton, Portage, Chemung, and Catskill Groups. By James Hall, State Geologist and Palæontologist. Assisted by John M. Clarke.' 4to, lxiv. and 236 pages, 45 plates. Albany, N.Y., 1888. Together with a 'Supplement to Vol. V., Part 2, of the Palæontology of New-York State. Pteropoda, Cephalopoda, and Annelida,' 42 pages, and plates 114 to 129.

The groupings of families, genera, &c., are as follow:—

I. PHYLLOCARIDA.

A. CERATIOCARIDÆ.

I. CERATIOCARIS, McCoy, 1849. Occurring in the *Genessee* and *Portage* formations.

1. *C. longicauda*, Hall, p. 163, pl. 31, fig. 1.
2. *C. Beecheri*, Clarke, p. 164, pl. 31, fig. 3.
3. *C. (?) simplex*, Clarke, p. 165, pl. 31, fig. 2.

II. *Echinocaris*, Whitfield, 1880. Occurring in the *Hamilton*, *Portage*, and *Chemung* formations.

1. *E. punctata*, Hall, p. 166, pl. 27, fig. 10; pl. 28, figs. 1–7; pl. 29, figs. 1–8. Prof. Hall prefers to keep *punctata* rather than *armata* for the specific name (p. 170): see our Third Report, 1885, p. 360. The Mandibles of *Phyllocarida* are treated of at pp. 170, 171; pl. 30, figs. 13–19.
2. *E. Whitfieldi*, Clarke, p. 172, pl. 29, figs. 20, 21.
3. *E. condylepis*, n. sp., p. 173, pl. 29, figs. 14–17.
4. *E. socialis*, Beecher, p. 174, pl. 30, figs. 1–12.
5. *E. sublævis*, Whitfield, p. 176, pl. 29, figs. 11–13.
6. *E. pustulosa*, Whitfield, p. 178, pl. 29, figs. 9, 10.
7. *E. multinodosa*, Whitfield, p. 180, pl. 29, figs. 18, 19.

The *Equisetides Wrightiana*, referred by Woodward and Jones to *Echinocaris* (Third Report, 1885, p. 360), is provisionally placed by Prof. Hall with *Stylonurus*, by reason of the character of the spinous elevations, pp. 161, 162.

III. ELYMOCARIS, Beecher, 1884. Occurring in the *Hamilton* and *Chemung* formations.

1. *E. capsella*, n. sp., p. 181, pl. 31, fig. 4.
2. *E. siliqua*, Beecher, p. 182, pl. 31, figs. 5, 6.

IV. TROPIDOCARIS, Beecher, 1884. Occurring in the *Hamilton* and *Chemung* formations.

1. *T. bicarinata*, Beecher, p. 184, pl. 31, figs. 7–12.
2. *T. interrupta*, Beecher, p. 185, pl. 31, fig. 13.
3. *T. alternata*, Beecher, p. 186, pl. 31, figs. 14, 15.

B. PINACARIDÆ.

I. MESOTHYRA, n.g. Occurring in the *Marcellus*, *Hamilton*, and *Portage* formations.

1. *M. Oceani*, n. sp., p. 187, pl. 32, figs. 1–6; pl. 33, figs. 4–7; pl. 34, figs. 1–5. Separated from *M.* (formerly *Dithyrocaris*) *Neptuni*, Hall, on account of some differences in the caudal appendages.
2. *M. Neptuni*, Hall, p. 191, pl. 32, fig. 7; pl. 33, fig. 1.
3. *M. spumcea*, n. sp., p. 193, pl. 32, figs. 8, 9; pl. 34, fig. 2.
4. *M. (Dithyrocaris ?) Veneris*, n. sp., p. 193, pl. 33, fig. 3.

[II. DITHYROCARIIS, Scouler, 1843.] In the *Hamilton* formation.

1. *D. Belli*, Woodward, p. 184 (Gaspé).

C. RHINOCARIDÆ.

I. RHINOCARIS, n.g. (J. M. C.) Occurring in the *Hamilton* formation.

- Rh. columbina*, n. sp., p. 195, pl. 31, figs. 16–21.
- Rh. scaphoptera*, n. sp., p. 197, pl. 31, figs. 22, 23.

D. DISCINOCARIDÆ.

I. SPATHIOCARIS, Clarke, 1882. In the *Portage* formation.

1. *Sp. Emersoni*, Clarke, p. 199, pl. 35, figs. 12-18.

II. DIPTEROCARIS, Clarke, 1882. In the *Portage* and *Chemung* formations.

1. *D. pennæ-Dædali*, Clarke, p. 200, pl. 35, fig. 24.
2. *D. Procne*, Clarke, p. 201, pl. 35, figs. 25-27.
3. *D. pes-cervæ*, Clarke, p. 202, pl. 35, figs. 20, 21.

II. PHYLLOPODA.

A. LIMNADIADÆ.

I. ESTHERIA, Rüppel, 1857. In the *Hamilton* formation.

1. *E. pulex*, Clarke, p. 206, pl. 35, figs. 10, 11.

II. SCHIZODISCUS, n.g. (J. M. C.), p. 203. In the *Hamilton* formation.

1. *S. capsæ*, n. sp., p. 207, pl. 35, figs. 1-9.

Second Report of the Committee, consisting of Mr. S. BOURNE, Professor F. Y. EDGEWORTH (Secretary), Professor H. S. FOXWELL, Mr. ROBERT GIFFEN, Professor ALFRED MARSHALL, Mr. J. B. MARTIN, Professor J. S. NICHOLSON, Mr. R. H. INGLIS PALGRAVE, and Professor H. SIDGWICK, appointed for the purpose of investigating the best method of ascertaining and measuring Variations in the Value of the Monetary Standard. (Drawn up by Mr. GIFFEN.)

In their reports last year the Committee discussed fully the theoretical aspects of the problem of measuring variations in the value of the monetary standard. It was abundantly clear, from this discussion, they think, that even if statistical data were more complete than they are the question is a most complicated and difficult one: how to measure variations in the value of the monetary standard would in no case be a simple matter. They desire now to report on one or two of the more definite issues involved as connected with problems of immediate practical interest, of which it may be possible for the public to attempt an approximately correct practical solution.

The main practical uses for which the measurement of variations in a monetary standard has been desired appear to be the following:—

1. The fixation of rents or other deferred payments extending over long periods of time, for which it has been desired to obtain a currency of a more stable sort than money is supposed to be. This has been a practical question of great importance from the days of Fleetwood's 'Chronicon Preciosum,' which begins, as is well known, with a remarkable case of conscience—whether a man in order to receive a bursary or scholarship, for which a declaration that his private income does not exceed, say, five pounds a year, is required, is justified, the value of money having fallen proportionately, in making the declaration upon an income not exceeding thirty pounds a year. In recent times there is at least one instance of a different standard from metal being deliberately

substituted on a large scale, viz., the tithe averages, these being made to vary with the value of grain, so that in effect the tithe is so much grain, and not so much money. The Scotch Fiars prices have existed for more than two centuries for similar purposes.

2. To enable comparisons to be made between the value of money incomes in different places, which is often an object of great practical interest, not only individuals contemplating residential changes having to consider it, but Governments and other large spending bodies, spending money in widely distant places, having to do the like. Apart from directly business issues of this sort, such questions are of obvious practical interest to economic students, and through them to the general public.

3. To enable historians and other students making comparisons between past and present to give an approximate meaning to the money expressions which they deal with, and say roughly what a given fine, or payment, or amount of national revenue or expenditure in a past age would mean in modern language. To the student of history from the economic point of view some such method of giving a meaning to money expressions is indispensable.

And it has been seen theoretically that the only way to accomplish these objects is to form 'index-numbers,' that is, to substitute for money some other measure by which the value of money or any other single commodity relative to an aggregate of commodities may be ascertained. If all commodities could be included in such an index-number, and a proper weight assigned to each, and if the same commodities existed in the same proportion in past times and at different places as exist now at a given place, the new measure would be perfect for the purposes required, *provided that there were any possibility of ascertaining the prices themselves*, and approximately, apart from this special difficulty of obtaining prices, there may be such a new measure which will be useful, though it is not ideally perfect. For the purposes above stated, it is obvious something that is very useful may be obtained without even an approach to ideal perfection. The intervals of time and the differences of place may be so great that useful distinctions may be drawn out, even although there is a wide margin of error, and although it is certain that from such causes as the introduction of new commodities and the dropping out of others, and the continual changes in the proportions in use of all the others, absolutely exact comparisons cannot be made.

But, apart from all such difficulties, which were fully discussed in last report, it may be stated broadly that hitherto both students and practical politicians have been limited even more effectually in their means of measuring variations in the monetary standard by the absolute deficiency of the data. It is practically, for instance, unnecessary for them to consider whether they are to use the retail prices which must be used if an ideal index-number based on *desiderata* is to be employed, because there is no complete record of retail prices even at the present time, and certainly there are no such records of retail prices in many different places, and going back over historical periods. Similarly there can be no question, as regards the past or present, of such an ideal standard as that suggested by Professor Nicholson, which depends on a valuation of the property in a country, for no valuation approximately accurate enough for such a purpose could be made in any country at the present time, much less could it be carried backwards for any lengthened period.

For these reasons practically the best must be made of wholesale

prices, for these are the only prices of which there are records—of which it may almost be said there can be records, retail prices being subject to many difficulties, including the degree of 'retailing' which may exist, to become the basis of records capable of solving the practical problems stated. "

In actual fact students and politicians have been still more limited. There are prices and prices. Practically it is found that only the prices of leading commodities, capable of being dealt with in large wholesale markets, can be made use of, while the assumption must be made, so numerous and varying are qualities, that certain articles may be taken as types. For instance, in dealing with the values of wheat it is convenient to take *English* wheat, as represented by the *Gazette average*, as a type, and assume that all wheat sold in England varies in price as English wheat does; but the assumption may not be quite correct, while the *Gazette average* itself, if we look at the question historically, only goes back a hundred years, and previous to that the historical student must fall back on the records of the value of wheat at a particular place, such as Windsor. Even greater difficulties arise with regard to other articles, while for some purposes the prices of large masses of articles, which are obtained by such means as the division of the aggregate quantities of the imports by aggregate values, are deficient, owing to the changes in the qualities of the constituents of the group from year to year or from period to period. In dealing with the question practically, therefore, those concerned must always have an eye upon the data and consider what is practically obtainable and what use may be made thereof.

Looking at the subject in this way, then, the most important conclusion seems to be that for such practical purposes as those above mentioned the methods already followed may be and have, in fact, been approximately successful. With improvements they may be made more useful, although ideal perfection is unobtainable, and even inconceivable. What has to be considered is that the prices of leading commodities are likely to vary on the average as all commodities vary on the average; that, if such commodities are selected without bias, the result, as regards the selected articles, may be accepted as representative of the average result; that wholesale and retail prices will vary in much the same way, and that consequently the mean of a number of prices taken almost at random, if there is a sufficient number to get rid of chance errors, may be depended on to measure variations in the monetary standard in lieu of a standard composed of all articles whatsoever, each receiving its proper weight. Rough approximations only are possible, but according to the logic of statistics the defectiveness of the statistical data, though it has to be recognised, is not an insuperable barrier to the adoption of rough approximations which are valuable. Let us see what has been accomplished.

The '*Chronicon Preciosum*,' dealing with the chief articles only, as to which records of price happened to remain, and using a plan of means in which each article was considered to be of equal importance, showed approximately that the value of money had changed from century to century; that, measured by the common articles of trade and consumption, a sovereign did not go so far in the time of that book as it did several centuries before—that it only commanded a sixth part of the average of leading commodities which it had commanded several centuries

previously. The whole calculation was very rough, but it conveyed a sound historical idea which was useful and fruitful in the absence of a better. It also may be held to justify the action Bishop Fleetwood suggested in the case of conscience referred to.

Adam Smith, substituting wheat alone as a standard, was able to show changes in the purchasing power of money, though, of course, it would have been better to use more articles. Still the conclusion for wheat alone, considering its great importance in those times, was good enough to prove a change in the value of money.

Sir George Evelyn's index-number, submitted to the Royal Society in 1798, led to a broad conclusion not substantially different from those of Adam Smith and Fleetwood.

In later times the researches of Professor Jevons and the index-numbers of the *Economist*, Sauerbeck, and others, have demonstrated conclusively that there has been a common movement in the prices of leading wholesale commodities, proving a variation in the value of money, relative to an aggregate of these leading commodities, which can, no doubt, be made use of by historians and economic students when they wish to give meaning to the money expressions of different periods. There is, no doubt, a great lack of quantitative exactness in the past discussions, and it may be fairly urged that more consideration should be given to the question of how to allow for the changes in the efficiency of the human unit—a question raised by Adam Smith's selection of wheat on the express ground that the labour employed in producing a quarter of wheat had remained unchanged; but to suggest that a particular method which has produced useful ideas may be improved upon and made to yield more exact results is not to show that it is useless.

The Gazette average prices of grain used for the tithe averages have also proved conclusively, on a large scale, that a currency different from money may be practically made useful in deferred payments—that the process can be put into a working Act of Parliament.

The considerations we have to suggest as now most important practically, in preparation for more exact and complete measurements in the future, are the following:—

1. In the absence of retail prices—which it would be most convenient to use in forming a standard of *desiderata*—use must necessarily be made of wholesale prices only. No other prices are obtainable, and those prices must be preferred, in the selection of typical articles, where the records are best.

It appears, however, from the best consideration of the subject, that the differences likely to be made from the true result which would be obtained from a more complete record of prices are not likely to be material. On this head the Committee would refer to a paper by Mr. Edgeworth, which has been prepared for their use, and which is appended. The prices of articles taken without bias from a group are likely to be fairly representative of the average course of prices of that group.

2. While an index-number assigning relative weight to different articles so selected is an important means of arriving at a useful result, it cannot be said, in the present state of the data on the subject, to be an altogether indispensable means. The articles as to which records of prices are obtainable being themselves only a portion of the whole, nearly as good a final result may apparently be arrived at by a selection with-

out bias, according to no better principle than accessibility of record, as by a careful attention to weighting. On this head the Committee may refer to the above paper of Mr. Edgeworth, which seems conclusive on the subject.

3. Practically the Committee would recommend the use of a weighted index-number of some kind, as, on the whole, commanding more confidence. But they feel bound to point out that the scientific evidence is in favour of the kind of index-number used by Professor Jevons—provided there is a large number of articles—as at present insufficient for the purpose in hand. Nothing is more remarkable in the comparisons of the recent index-numbers than the correspondence of the curves of general course of prices indicated. A *weighted* index-number, in one aspect, is almost an unnecessary precaution to secure accuracy, though, on the whole, the Committee recommend it.

4. The Committee have had before them a suggestion for a new index-number, which might be used for some official and private purposes, based on the practical considerations referred to, and making use of the best wholesale prices, while having regard to the ultimate standard of *desiderata*. The nature and object of this index-number is explained in the accompanying memorandum, which has the general approval of the Committee, though they do not consider it necessary here to go into all the details. The object is to provide something for which it would be possible to obtain and publish official prices, and by reference to which contracts could be made, and it is submitted for discussion and future reference.

5. It would be most desirable to supplement any such index-number by a good statistical account from time to time of the aggregate income of the people and the relative numbers and aggregates of incomes of different amounts. In some index-numbers in past times the wage of a day-labourer is inserted as one of the articles. This may have been correct enough for some purposes, and in the circumstances would not prevent the index-number from indicating the general changes in the value of money in the periods compared. But the more useful method would seem to be to distinguish between the human unit in production and the thing produced. Among the most important comparisons for which such figures are used at all are the effectiveness of labour at different times and places, and the command of the labourer or other earner over the amounts produced; and these comparisons can only be made when an independent standard of the production and consumption of the labourer is set up, with which his earnings may be compared. No argument is needed to show that, along with index-numbers as to prices of commodities, there should be an endeavour to ascertain the aggregate earnings of a community and the distribution of the earnings so as to show on the one side the command over commodities which different classes possess—the real as distinguished from the nominal incomes—and on the other side the relative effectiveness of the labour of a community at different times or of one community compared with another.

The matters referred to them not being fully exhausted, the Committee would recommend their reappointment, with a view especially to considering the question of an official index-number or numbers for future use in contracts, and what are the chief points to be looked at in the necessary enactments, both for obtaining the necessary price data and for settling forms in which contracts may be expressed.

MEMORANDUM ON AN OFFICIAL INDEX-NUMBER.

TABLE FOR THE CONSTRUCTION OF AN INDEX-NUMBER.

Statement showing the estimated amount of the expenditure on the undermentioned articles in the United Kingdom and the proportion of the amount in each case to the total expenditure on all such articles, with suggestions for an index-number based approximately on the proportions stated, but with modifications so as to substitute percentages in round figures; showing also the description of the specific wholesale article, the price of which it is proposed to use in the calculation of the index-number; giving also the price-list or other source from which quotations are to be obtained.

1	2	3	4	5	6	7
Heads of articles	Articles consumed or used up	Estimated expenditure per ann. on each article	Percentage of each amount in column 3 to total	Relative importance proposed for each article in index-number reduced to percentages	Description of the specific article of which the price is to be quoted as typical	Price-list or other source for price quotations
Breadstuffs	Wheat . . Barley ¹ . . Oats . . Potatoes, rice, &c. }	£ 000,000 60 30 50 50	6·5 3·25 5·4 5·4	5 5 5 5 } 20	English wheat . . . " barley . . . " oats . . . " potatoes . .	Gazette average " " " " Average import price

Indigo imported . . Flax imported . . . Palm oil imported . Caoutchouc imported	Average import price " " " " " " " " " " " " " " "
	Totals .	920	100	100		

In this table the first column indicates six leading genera which comprehend the twenty-seven classes of articles specified in the second

¹ There is a large consumption of barley, exclusive of its use in the manufacture of beer.

column. These articles are either finished products (things ready for consumption, like cheese and milk) or *represent* such things by entering into their production, as coal (used in manufacturing) and timber, for instance, go to the production of houses and furniture.

The third column gives in round numbers (000,000's being omitted) the average national expenditure on each class of article at present and for the last few years, and presumably also for the immediate future the *proportions* at least, if not the absolute amounts, of expenditure (such proportions, as shown in Mr. Giffen's reports on the variation in the prices of exports and imports, remaining pretty constant during a period of years). In the estimated amount of consumption allowance is made for the addition to the value made before the articles are in the form in which they are finally consumed.

In column 4 these amounts (or proportions) are reduced to percentages (of the total amount expended on such articles).

In column 5 the relative importance proposed to be assigned to each article in the index-number is stated, mainly on the basis of the percentages in column 4, but with modifications so as to substitute even figures for the convenience of handling.

In column 6 the specific articles are described, of which it is proposed to obtain the prices as typical of the group really included on the corresponding line in column 2. Wheat, for instance, consists of many different kinds and qualities; the one quality and kind it is proposed to quote as typical of the whole is English wheat as returned officially to the Comptroller of the corn returns, which itself no doubt comprises many qualities. Of iron, again, there are innumerable qualities and kinds; it is proposed to take Scotch pig-iron, in which there are large dealings, as typical of the whole. The same with other articles. In most cases large groups are dealt with because the article selected is the average imported or exported, which includes many qualities, but it should be distinctly understood that in any case the most that can be done is to select specific articles which are typical of large groups.

In column 7 the source from which the quotation of the specific articles mentioned in column 6 is to be obtained is stated.

The above is of course only a rough suggestion for an index-number. Even if the method is generally approved of, many questions might be discussed as to the amounts of the annual consumption of each group of articles specified in column 2, as to the relative importance to be assigned practically in column 5, and as to the selection of the article in column 6 which is to be treated as typical of the group. It would be possible to introduce two or more quotations instead of one for a particular group if thought desirable, but this would be troublesome in working. For practical purposes there must not be too many articles. Mr. Edgeworth's mathematical deductions as to the consequences of taking the price of an article selected at random from a group, instead of the general average course of prices for the group, appear to justify the expediency of this procedure.

Were such a general index-number introduced, and prices calculated upon it backwards and forwards, it would be easy to rearrange it for any special purpose, such as to give more or less weight to one or more groups according as they are assumed to enter into the consumption of a particular class of persons whose position at different times as affected by the course of prices is to be specially investigated. The index-number could

also be compared with other index-numbers upon some other objective basis, such as the relative importance of each article in the import and export trade of a country; and index-numbers for one country and place could be compared with those for other countries or places. The index-number now suggested is only put forward as a convenient one, illustrating the variations in prices in England according to what is called the standard of *desiderata*, and which could be made use of—not neglecting others—in many investigations.

It would also be an index-number on which, if people were so inclined, they could make contracts in a way analogous to the contracts for the commutation of tithe; in which the tithe is made to vary according to the prices of corn. To make the index-number useful for this purpose an Act would have to be passed prescribing the way in which the prices are to be obtained and published, and defining and giving a form for the contracts which might be made for payments, to vary according to the variation in the aggregate index-number. This would be a practical Tabular Standard such as Joseph Lowe, Jevons, and lately Professor Marshall, have suggested.

All such index-numbers are liable to the observation that innumerable articles are, and must be, in the nature of things, wholly excluded. The variety of small articles is almost infinite. The assumption may also be made, I think, that on balance the permanent tendency is for such articles on the average, through the progress of invention, to increase in aggregate importance in proportion to the other articles which can be got into an index-number and, at the same time, individually to fall relatively in price. In investigations general facts of this kind would, of course, have to be borne in mind as qualifying deductions based upon the precise figures which the index-numbers may give. People making contracts based on index-numbers would also require to study what the effect would be likely to be on the result they wish to arrive at.

MEMORANDUM BY THE SECRETARY, PROFESSOR F. Y. EDGEWORTH, ON THE ACCURACY OF THE PROPOSED CALCULATION OF INDEX-NUMBERS.

Appendix showing the extent and significance of the difference between the Committee's scheme and others	213

The usefulness of our result will be enhanced by an estimate of its accuracy. It would be desirable, if possible, to ascertain a numerical limit which the *error*¹ incurred by our calculation cannot possibly, or at

¹ The use of the term 'error' to denote a deviation from an unknown ideal is somewhat infelicitous. But the advantage which the term has in being familiar to

least with any reasonable probability, exceed. But it is doubtful whether such a limit admits of being fixed with precision. The erroneousness of the conclusion could only be ascertained by inference from the inaccuracy of the premises. But it is difficult to appreciate with mathematical precision the error to which our data are liable. We may, however, argue that, if the erroneousness of the premises is approximately of a certain amount, if the error of the data is of a certain *order*, then the error of the conclusion will be of a certain other order.

Of course, it will be understood that, in attempting to evaluate mathematically the error of our result, we mean its deviation from the real numerical value of that quantity which we have here taken as our *quæsitum*: namely, the total national expenditure on material products at any given time comparative with an initial epoch (abstraction being made of any change in the total quantity of products which may have occurred between the epochs).¹ The philosophical error which may be committed by taking this sort of index-number as our ideal is the subject of another sort of analysis.

The subject of our investigation being thus defined, we may show that the erroneousness of the result is *less* than that of the data. There are two lines of proof converging to the truth of this theory. *First*, we may reason *à priori* by the Calculus of Probabilities that the index-number is subject to a smaller percentage of error than the weights and price-variations (given or referred to in columns 5 and 6 of the table). *Secondly*, this deduction may be verified by actual trial. We may assign a certain set of weights and price-variations as correct, and construct several sets of variants diverging from the 'correct' figures in haphazard fashion. Then, operating with each set of variant data, we may calculate several variant index-numbers. These, it will be found, diverge less—that is by a smaller percentage—from the correct index-number than any set of variant data from the corresponding correct datum.

The second part of the evidence cannot be fully appreciated without the prior reasoning. By itself it conveys only a moiety of the truth. Those who are content with that fraction of knowledge are advised to skip the small type and close reasoning of the immediately following paragraphs and to pass on to the more easily read lessons of experience.

The index-number which is the result of our calculation is subject to a less error than the data which enter into it, for two reasons. *First*: The numerator and denominator of the fraction which constitutes the index-number form each an aggregate of elements or parts, whereof each element is subject to a presumably independent error. Now, by a well-known principle of the Calculus of Probabilities, the percentage error of such an aggregate is less than the percentage error incident to each element (or at least to an element of average erroneousness). This principle applies to the errors both of the *weights* and the *observations* (price-variations). The next consideration applies only to the former class of data. An error in any *weight* affects both the numerator and denominator in the same direction, whether of excess or defect, and thus is to a certain extent self-corrected.

This reasoning may be exhibited more fully by the aid of symbols. Let us put the series $p_1, p_2, \&c. \dots p_n$ for the *real* price-variations. These price-variations

the student of Probabilities may, it is hoped, preponderate over the disadvantage that it suggests to the general reader a more gross, blameworthy, and avoidable mistake than is contemplated here.

¹ For a more exact definition of the *quæsitum*, see in the First Report of the Committee the formula for the 'Principal Standard.'

may be conceived as percentages obtained after the manner of Mr. Palgrave (see Table 26 of Memorandum in Appendix to 'Third Report of the Commission on Depression of Trade') by multiplying the ratio $\frac{\text{New price}}{\text{Old price}}$ by 100. Let us denote

the *apparent* price-variations, the erroneous observations, as $p_1(1+e_1)$, $p_2(1+e_2)$, . . . $p_n(1+e_n)$, where e_1, e_2 , . . . e_n are each positive or negative errors, usually proper fractions. Similarly let w_1, w_2 , &c., be the *real* weights; and $w_1(1+\epsilon_1)$, $w_2(1+\epsilon_2)$ &c., be the apparent, or erroneous, weights.

The index-number obtained from such data is

$$\frac{w_1(1+\epsilon_1) \times p_1(1+e_1) + w_2(1+\epsilon_2) \times p_2(1+e_2) + \&c.}{w_1(1+\epsilon_1) + w_2(1+\epsilon_2) + \&c.}$$

Alike in the numerator and denominator of this expression we may segregate the *correct* and the *erroneous* portion; and reason by the first of the principles above mentioned that the incorrect portion is of a smaller order than the sum of the correct terms (the number of observations being sufficiently great). Accordingly it will be allowable to expand by Taylor's Theorem and neglect higher terms. We shall thus obtain a simple expression for the error of the resultant index-number in terms of the errors to which each class of the data is liable.

This investigation may be broken up into three steps: we may consider successively three cases in an order of increasing complexity. First (1) we shall suppose that the weights only are liable to error. Then (2) we shall introduce the circumstance that the observations, the price-variations, are themselves incorrect. Lastly (3) we shall take account of the fact that certain categories of articles may be altogether unrepresented.

(1) Under the first head we shall first consider the simple case when the weights are really equal, though apparently somewhat unequal. In this preliminary case the symbolic expression above written becomes simplified by the disappearance both of the e 's and the w 's. Expanding and segregating the heterogeneous elements in the manner indicated, we may write our result thus:—

$$\frac{p_1 + p_2 + \&c.}{n} \left\{ 1 + \frac{p_1\epsilon_1 + p_2\epsilon_2 + \&c.}{p_1 + p_2 + \&c.} - \frac{\epsilon_1 + \epsilon_2 + \&c.}{n} \right\},$$

where the term outside the brackets is the *correct* index-number, and the difference of the second and third terms within the bracket is the error of the index-number: the relative error, as it may be called, or (if multiplied by 100) the percentage error, in symbols $\frac{\Delta I}{I}$, if I is the correct index-number. The result obtained may be written

$$\frac{\Delta I}{I} = \frac{Sp}{n} \left\{ 1 + \epsilon_1 \left(\frac{p_1}{Sp} - \frac{1}{n} \right) + \epsilon_2 \left(\frac{p_2}{Sp} - \frac{1}{n} \right) + \&c. \right\}.$$

In this expression call the factors of ϵ_1, ϵ_2 , &c., respectively $\frac{1}{n}E_1, \frac{1}{n}E_2$, &c.

Then $\frac{\Delta I}{I}$, the error whose magnitude we have to estimate, is $\frac{1}{n}(E_1\epsilon_1 + E_2\epsilon_2 + \&c.)$.

To determine the probable and improbable limits of this quantity we require to know the magnitude, or at least the average extent, both of the E 's and the ϵ 's. The former datum depends upon the dispersion of the observations (the price-variations) about their mean. For any E , e.g.,

$$E_r = n \left(\frac{p_r}{Sp} - \frac{1}{n} \right) = n \frac{\left(\frac{Sp}{n} - p_r \right)}{Sp} = \frac{\left(\frac{Sp}{n} - p_r \right)}{\frac{Sp}{n}}$$

the deviation or *error* incurred by the individual price-variation as compared with

the average of a whole set; *relative* to (divided by) the average. Such a deviation might be symbolised as $\frac{\Delta p}{p}$, if we put p for the average price-variation.

We may now proceed in two ways: (a) we may either suppose the deviations E_1, E_2 , ascertained for the particular year or epoch to which the calculation in hand may refer; (β) or we may seek a measure for general use, and available without the trouble of examining the dispersion of the price-variations for a particular year. In either case we are to regard the ϵ 's as errors grouped in random fashion about a mean, which is zero. The coefficient which measures the dispersion of these errors, the *modulus* for the ϵ -fluctuation, must be supposed knowable. Call it κ .

(a) On the former understanding, we are to regard E_1, E_2 , &c., as known factors. Accordingly by a well-known theorem we have for the *modulus*, which measures the extent of the error,

$$\begin{aligned} & \frac{1}{n} (E_1 \epsilon_1 + E_2 \epsilon_2 + \&c.), \\ & \frac{1}{n} \sqrt{E_1^2 + E_2^2 + \&c.} \times \kappa, \\ \text{or} \quad & \frac{1}{\sqrt{n}} \sqrt{\frac{E_1^2 + E_2^2 + \&c.}{n}} \times \kappa. \end{aligned}$$

(β) Otherwise we are to regard E_1, E_2 , as samples, so to speak, taken from an indefinite number—a complete series (in Dr. Venn's phrase) of E 's. We must suppose the coefficient of fluctuation, or modulus, for this series to be given by prior experience. Let it be C . Then we may put as the most probable value for the measure or *modulus* of $\frac{\Delta I}{I}$, the error under consideration,

$$\frac{1}{\sqrt{n}} \times \frac{C}{\sqrt{2}} \times \kappa.$$

But this *most probable* measure cannot safely be used as the *best* measure. We must take into account that the real measure *may* be larger, and accordingly that, by adopting the measure described as 'most probable,' we may be underrating the probability of each extent of deviation (from zero) to which the quantity $\frac{1}{n} [E_1 \epsilon_1 + E_2 \epsilon_2, \&c.]$ is liable. However, the error thus introduced is only of the order $\frac{1}{\sqrt{n}}$, that is, the $\frac{1}{\sqrt{n}}$ -th part of the magnitude to be evaluated. Now that degree of error has been already incurred by the neglect of the higher terms in the expansion of $\frac{\Delta I}{I}$. Accordingly it would be nugatory to apply correctives to the error now under consideration.

We have now to introduce the circumstance that the weights, both real and apparent, differ from unity. It is easy to see that in the new expression for $\frac{\Delta I}{I}$ the coefficient of any weight-error ϵ_r is $\frac{w_r p_r}{Sw p} - \frac{w_r}{Sw}$; which may be put in the form $\frac{w_r}{Sw} E'_r$, where E'_r is now the proportional deviation of p_r from the *weighted* mean of the p ; viz., $\frac{Sw p}{Sw}$. Accordingly the modulus of $\frac{\Delta I}{I}$ becomes

$$\frac{\sqrt{w_1^2 E'^2 + w_2^2 E'^2 + \&c.}}{Sw} \kappa.$$

In evaluating the coefficient of κ there are, as before, two courses. Either (a) we operate upon the known values of E'_1, E'_2 , &c., for the particular year or epoch with which we are concerned; or (β) we may make a general estimate based upon

several years' experience, and roughly applicable to the unexamined data of any year.

(a) In the former case there is nothing more to be said, except that it will be legitimate in the evaluation of the modulus to put for $w_1, w_2, \&c.$, their *apparent* values; which may be written $w_1 + \Delta w_1, w_2 + \Delta w_2, \&c.$ For the error thus introduced into the modulus is of a neglectible order.

(b) The general expression in terms of the E-fluctuation is found by considering that the most probable value of the quantity under the radical sign in the last written expression is $\sqrt{(w_1^2 + w_2^2 + \&c.) \frac{C^2}{2}}$, where $\frac{C^2}{2}$ is the mean square of error measured, not, as before, from the simple (arithmetical) mean (of many batches of p 's), but from the weighted mean $\frac{Spw}{Sw}$; a difference which may easily be shown to be for our purpose of an order which may be neglected.

This may be proved thus:

The deviation of any p from the Weighted Mean—the relative or proportionate deviation— E'

$$= \frac{\frac{Spw}{sw} - p_r}{\frac{Spw}{sw}}.$$

This ratio may be thus expressed in terms of E_r , the deviation of p_r from the *Simple Arithmetic* Mean. Put v for the difference between the weighted and simple means. Then we have

$$E'_r = \frac{\left(\frac{Sp}{n} - p_r\right) - v}{\frac{Sp}{n} - v} = \frac{E_r - \frac{v}{p}}{1 - \frac{v}{p}},$$

if we put p for the Arithmetic Mean of the p 's.

$$\text{Now } v = \frac{Sp}{n} - \frac{Spw}{Sw} = \frac{p_1 + p_2 + \&c.}{n} - \frac{p_1 w_1 + p_2 w_2 + \&c.}{w_1 + w_2 + \&c.}.$$

Substitute for p_1 its value $p(1 + E_1)$ (where p is the Arithmetic Mean of the p 's); and we have

$$\begin{aligned} v &= p \left[\frac{E_1 + E_2 + \&c.}{n} - \frac{w_1 E_1 + w_2 E_2 + \&c.}{w_1 + w_2 + \&c.} \right] \\ &= \frac{1}{n} p E_1 \frac{\frac{Sw}{n} - w_1}{\frac{Sw}{n}} + \frac{1}{n} p E_2 \frac{\frac{Sw}{n} - w_2}{\frac{Sw}{n}} + \&c. \end{aligned}$$

Put for the relative deviation of any w from the Arithmetic Mean of all the w 's (the coefficient of $\frac{1}{n} p E_r$ in the last written expression) η_r . Then we have

$$v = \frac{1}{n} p [E_1 \eta_1 + E_2 \eta_2 + \&c.].$$

The expression in brackets hovers about the value zero according to a law of error whose modulus is $\frac{\sqrt{n} C \chi}{\sqrt{2}}$; where C , as before, is the modulus of the E 's, and $\frac{\chi^2}{2}$ is

the mean square of the η 's. Hence $\frac{v}{p}$ is of an order \sqrt{n} times smaller than $C \chi$.

But from the equation connecting E' and E it appears that the sum of squares $E_1'^2 + E_2'^2 + \&c.$ which occurs in the complete expression for the modulus of $\frac{\Delta I}{I}$ may be written

$$\frac{SE_r^2 + n\left(\frac{v}{p}\right)^2}{\left(1 - \frac{v}{p}\right)^2};$$

whence, as $SE_r^2 = n \frac{C^2}{2}$, it appears that the influence of $\frac{v}{p}$ may be neglected, n being supposed large.

We may therefore write

$$\text{Modulus of } \frac{\Delta I}{I} = \frac{\sqrt{Sw_r^2}}{Sw} \frac{C}{\sqrt{2}} \kappa;$$

or, employing the notation which we had lately occasion to introduce:

$$\text{Modulus of } \frac{\Delta I}{I} = \frac{1}{\sqrt{n}} \times \sqrt{1 \times \frac{\chi^2}{2}} \times \frac{C}{\sqrt{2}} \times \kappa.$$

This formula may be employed to utilise present as well as past experience. If we treat $\frac{\chi^2}{2}$ and $\frac{C^2}{2}$ as respectively the mean square of deviation obtained from the set of weights and price-returns entering into the index-number which we are computing, we shall thus have an approximate formula more convenient than the complete expression for the Modulus.

(2) We have now to introduce the circumstance that each p is liable to an error pe . Each element of error of the form Πe_r is now aggravated by an element of the form $P e_r$. Accordingly the modulus of the total error will be $\sqrt{\Pi^2 + P^2 c^2}$, where κ and c are the moduli for the independent partial errors respectively, Π is the coefficient of κ in the expression for the modulus of $\frac{\Delta I}{I}$ in case (2) and P^2 is easily seen to be equal to $\frac{Sw_r^2 p_r^2}{(Sw p)^2}$.

There may now be required, as before, a general formula applicable without any examination of the prices and weights on a particular occasion; or without other data than the coefficients expressing the dispersion of the prices and weights respectively. With this view, employing the notation already explained, and rejecting terms which may be shown to be of an inferior order, we may put for

$$\frac{Sw_r^2 p_r^2}{(Sw p)^2} \text{ the expression } \left(1 + \frac{\chi^2}{2}\right) \left(1 + \frac{C^2}{2}\right).$$

Hence for the modulus of $\frac{\Delta I}{I}$ in the general case we have

$$\frac{1}{\sqrt{n}} \times \sqrt{1 + \frac{\chi^2}{2}} \times \sqrt{\frac{C^2}{2} \kappa^2 + \left(1 + \frac{C^2}{2}\right) c^2}.$$

(3) So far we have been estimating the errors due to the weights and prices of the articles which enter into our index-number not being accurate. We have now to take into account that not only are all those articles misrepresented, but also that certain other articles may be wholly unrepresented. For it is unlikely that all the classes of products which ought by rights to enter into an index-number can, even constructively, put in an appearance.

We have now to superinduce the error due to such omission upon the errors already estimated. To effect this we proceed in the same way as when compounding the errors proper to our first and second headings. That is, we shall separately evaluate for the third species of error its modulus squared, or *fluctuation*, as the present writer has proposed to term this important coefficient. Then we shall add the third fluctuation to the sum of the two preceding: that is, to the square of the formula given at the end of the second heading.

To find the fluctuation proper to the third heading, let us begin with the simple case in which the weights are all equal. As before, let Sp represent the sum of the 1888.

observed (comparative) prices; let n be their number; and for $\frac{Sp}{n}$ put simple p . Let $S'p$ be the sum, and n' the number, of the *unobserved* prices. Then the error incurred by putting p for the Mean of all the prices, the relative error $\frac{\Delta I}{I}$, is

$$\left\{ \frac{Sp + S'p}{n + n'} - \frac{Sp}{n} \right\} \div \frac{Sp + S'p}{n + n'}.$$

The most probable value of this expression is zero; while its *fluctuation* is found to be, in terms and by methods already explained,

$$\frac{1}{n} \times \frac{2nn'}{(n + n')^2} \times C^2.$$

Now superadd the circumstance that the weights are various, dispersed about their mean according to the modulus χ . The effect of this attribute is to multiply the fluctuation last written by $1 + \frac{\chi^2}{2}$. The resulting expression is to be added to the square of the formula given at the end of heading (2). The effect of this addition is to insert a new term under the last radical in the formula for the Modulus. This new term is

$$\frac{2nn'}{(n + n')^2} C^2.$$

This formula will require modification, if there is reason to believe that the omitted articles have not the same average weight as those which are included; for instance, if, as is likely, the omissions are many in number, but inconsiderable in weight.

It will be noticed that in passing from (the dispersion of) the observed prices and weights to what has not been observed there is an inductive hazard greater than is involved by solutions of cases (1) and (2) in their more exact form, and while we suppose (as in the examples which will be adduced below) that the errors of weight and price emanate from regular and stable sources, so as to admit of safe prediction.

As in case (2), we may suppose the coefficients χ and C based either on prior experience or on the data appertaining to the particular calculation which is in hand.

It will be observed that these coefficients do not contribute equally to the resultant error represented by our formula. C , expressing the dispersion of the prices, is more efficacious than χ , appertaining to the weights. Similarly c , the measure of the error incident to the prices, affects the error of the index-number more than κ , the corresponding modulus of the weights.

It is proposed now to illustrate the formulæ which have been given by working a few examples. In these examples the statistical materials, the prices and weights, are taken out of Mr. Palgrave's *Memorandum*, from tables 26 and 27 respectively. The unstatistical arbitrary assumptions which will be made are that any price, and likewise any weight, is as likely as not to be out, in excess or defect, of the true figure by 10 per cent., but very unlikely to be out by 40 per cent., or, more exactly, that the apparent values fluctuate about the real one in conformity with a modulus which is 21 per cent.

Of the immense variety of cases which might be constructed by combining in different ways the attributes which define the preceding paragraphs, it will be sufficient here to discuss the most important case (2) of both weights and prices subject to error—divided into two species, according as (a) we utilise all the data special to the calculation in hand, or (β) content ourselves with the most summary estimate.

Let us apply these tests to Mr. Palgrave's computation of a weighted mean for the year 1885 (*Memorandum* in Appendix to *Third Report on the Depression of Trade*). First, according to method (a), the expression for the (proportionate) error due to a particular element of the index-number, the weight and price of a particular commodity, is

$$\epsilon_r \frac{w_r}{Sw_p} \left[p_r - \frac{Sw_p}{sw} \right] + e_r \frac{w_r}{sw} p$$

Whence, as the Modulus of the error to which the computed index-number is liable, we have—putting p' for the *weighted mean* of the price-returns, and remembering that c and κ are the Moduli of the errors e and ϵ respectively—

$$\frac{1}{Sw_p} \sqrt{Sw_r^2 (p' - p_r)^2 \kappa^2 + Sw_r^2 p_r^2 c^2}.$$

The w 's are given in Mr. Palgrave's column headed 'Relative Importance,' (table 27, year 1885). The p 's are to be extracted from his table 26. The weighted mean p' is, according to him, 76. And Sw_p is the sum of his column (for the year 1885), headed 'Comparative,' &c., *multiplied by 100*; that is 166,900. The rest of the expression above written is evaluated in the following table; of which the materials are taken from the sources named. The third column is formed by subtracting from each of the entries for 1885 in Mr. Palgrave's table 26—*e.g.*, 38 the price of cotton (comparative with 1865-9)—the weighted mean 76. The last three columns in Mr. Palgrave's table 26, relating to *Cotton Wool*, *Cotton Yarn*, and *Cotton Cloth*, are omitted, as they do not figure in this table 27, and, it may be added, cannot be supposed *independent* of the price of cotton. The last column in our table is formed by squaring each entry in Mr. Palgrave's column headed 'Comparative,' &c. (table 27, year 1885), and omitting the last digit:—

18	Tobacco . . .	29	8	+ 27	729	6	90
19	Wheat	410	1,681	- 16	256	430	5,856
Sums		2,200	6,256			3,781	43,142

According to the hypotheses above made let us put c and κ each = .21. Then for the sought Modulus we have

$$\cdot 21 \frac{\sqrt{378,100,000 + 4,314,200,000}}{166,900} = \cdot 21 \times \cdot 41 \text{ (nearly).}$$

Thus the error incident to each of the data has been reduced by a half in the result. It may be observed that the prices contribute much more largely than the weights to the total error. If we reduce the error incident to each price-return by a half, making its modulus .1, instead of .21, the total error of the result will be reduced by nearly a half—from modulus .086 to modulus .046. If we suppose the price-return to be quite correct, then the error of the result due to the weights alone would be nearly half as small again, namely, of modulus .025. This is agreeable to what was said above, that an error of the prices affecting only the numerator of the index-number is not, as in the case of the weights, compensated by an error affecting the denominator in the same sense.

Let us see now (β) how we should have fared if we had based our estimate on the grouping of the weights and prices in prior experience.

The dispersion of the price-returns, the coefficient C in the general formula, is thus to be found—in the case of the year 1884 for example. The arithmetic mean of the first nineteen entries in table 26 for 1884 is 81 nearly. The ‘differences’ and squares of differences are computed in the accompanying table. The mean square of difference 353 divided by the square of the mean 6561 forms an approximate, a *prima facie* value for $\frac{C^2}{2}$, namely, .04.

Name of Article	Differences		Squares of Differences

Sums	148	143	6,765

$$\text{Mean square of difference} = \frac{6765}{19} = 353.$$

For the year 1880, taken similarly as a random specimen, the mean (of the nineteen prices) is found to be 93.5, and the mean square of differences 434. Accordingly the value for $\frac{C^2}{2}$ is .05. Proceeding similarly for 1873, another year taken at random, we find for $\frac{C^2}{2}$ again .05. As the mean of the three values we may put .05.

To find the dispersion of the w 's we proceed similarly. The arithmetical mean is for every year $2200 \div 19$, or 116 nearly. The 'differences' are to be formed by subtracting this figure from each of the entries in Mr. Palgrave's column headed *Relative Importance*. The sum of the squares of the differences is to be divided by 19 for the absolute mean square of difference as it may be called. This result, divided by 116^2 , gives the mean square of error relatively to the mean weight. The values thus extricated for the years 1873, 1880, and 1884 respectively are, in round numbers, 354,000, 35,100, 357,000: each divided by 255,664 ($= 19 \times 116^2$); whereof the mean value is 1.38.

Substituting in the general or summary formula for the modulus of $\frac{\Delta I}{I}$ the values for C^2 and χ^2 just ascertained, and for C and κ the assumed value .21, we have

$$\frac{1}{\sqrt{19}} \times \sqrt{2.38} \times \sqrt{.05 \times .044 + 1.05 \times .044} = \frac{1}{4.36} \times 1.54 \times .22 \text{ (nearly)} = .077 ;$$

whereas the answer found by the more exact method was .086. This consilience seems greater than might have been expected, considering the small number of the elements entering into the computation—only nineteen—and the scantiness of the induction by which we determined the coefficients C and χ .

If we employ the summary formula as a short method of utilising the data special to the index-number of 1885, we shall find that $\frac{C^2}{2}$ as based upon the fluctuation of prices for this year is .08; and $\frac{\chi^2}{2}$ the mean square of deviation for the w 's is still 1.38. Hence, as the approximate expression for the modulus, we have

$$\frac{1}{4.36} \times 1.54 \times .21 \sqrt{1.16} = .08.$$

Thus we reach much the same result by the shorter as by the more tedious route.

We shall presently—in the portion of this paper addressed to the general reader—try an experiment calculated to verify our deductive reasoning—so far as a theorem in the Calculus of Probabilities can be verified by a single experiment.

We shall affect each of the elements in Mr. Palgrave's index-number for 1885, each weight and price, with a figure taken at random from a series of figures hovering about unity in conformity with a modulus equal to .21. Such a series the writer happens to have ready to hand: consisting of sums of twenty digits taken at random from mathematical tables, where the mean value is 90 and the absolute modulus 19. The relative modulus, therefore, the modulus for the series when we divide each aggregate by 90, is .21. Accordingly it will be sufficient to multiply each weight both in the numerator and the denominator with one of the sums (of twenty digits) taken at random, and similarly affect each price entering into the numerator, while the denominator is multiplied by 90.

To resume now, in popular language, this somewhat technical inquiry. The subject under investigation is the error to which our computation of index-numbers is liable—the error relative to, or per cent. of, the true value which we seek. We want to know, for instance, whether it is as likely as not that our calculation exceeds (or falls short of) the correct result by 10 per cent. of that result; whether it is very improbable that the excess (or defect) should be as great as 25 per cent.

The error thus conceived is found to depend in a definite manner upon six distinct circumstances. The erroneousness of the result is greater, the greater the inaccuracy of the data, viz., the weights, and the (comparative) prices. The erroneousness of the result is also greater, the greater the inequality of the weights, and the greater the inequality of the price-returns. Lastly, the result is more accurate, the greater the number of the data, and the smaller the number of omitted articles.

These circumstances are not all equally operative. Other things being the same, the inaccuracy of the price-returns affects the result more than

inaccuracy of the weights; and the inequality of the price-returns more than the inequality of the weights.

The only proof of the theory which can be offered to the unmathematical reader is to verify it by actual trial. We may assume a certain set of data as perfectly correct: then affect each of them with an error such that the modified datum is, say, as likely as not to be in excess or defect by 10 per cent.; is very unlikely to be out by 30 or 40 per cent.; and cannot, humanly speaking, be out by more than 50 per cent. A simple method of affecting a given set of figures with an error of this degree is to multiply each of them with a figure formed by adding together twenty digits taken at random from mathematical tables or statistical returns; dividing each product by 90 (the mean about which aggregates of twenty random digits hover). The data thus artificially affected with error are now to be used in the computation of an index-number, an erroneous number, which is to be compared with the result assumed to be true as having been deduced from the unfalsified data. A great number of such trials having been made, it will appear that the erroneous index-numbers deviate from the true one with the frequency and to the extent predicted by theory.

A specimen of this verificatory process is subjoined here. The data employed by Mr. Palgrave in his computation of an index-number for 1885¹ are assumed to be correct; then each datum is displaced or falsi-

¹ See above, p. 195.

fied in the manner above described, and a new (erroneous) index-number is deduced.

In this table the first column contains the names of articles in the order adopted by Mr. Palgrave in his table 27. The second column contains the 'weights' assigned by him under the heading of 'Relative Importance.' The third column consists of multipliers formed by adding twenty digits at random, and thus calculated to deflect the weights from their respective true values to the extent of, say, 12 per cent. on an average. The fourth column gives the new system of weights thus affected with error. The fifth column contains (comparative) prices taken from Mr. Palgrave's table 26. The sixth column furnishes a new set of multipliers assigned by chance. The seventh column gives the prices affected by error, and multiplied by 90 (the average value of the chance-multipliers). The eighth column gives the product of the erroneous weights and the erroneous prices ($\times 90$). The sum of this last column, 1,413,480,000, divided by ninety times the sum of the erroneous weights, which sum is 172,486, gives the erroneous index-number 81; whereas the true index-number, on the assumption here made that Mr. Palgrave's data are absolutely correct, is, as computed by him, 76.¹

Thus the falsified result is too great by $\frac{5}{76}$, or about 6 or 7 per cent. That is a result quite consonant with the theory which assigns such a *measure* of the error to be expected² that the result is as likely as not to be out by 4 per cent., and that the odds are only five to one against the error being so large as 8 or 9 per cent. It would have been nothing miraculous if the result had been out by *sixteen* per cent.; nothing more extraordinary than, for instance, the fortuitous sequence which may be observed in our third column of *eight* random aggregates falling below the average about which they should oscillate, namely 90.³

The same table furnishes another verification, if, making abstraction of Mr. Palgrave's weights, we assume the index-number calculated on the principle of the economist to be correct, and regard the figures in our sixth column as erroneous weights (the true weights being all equal). Upon this understanding we have the true result, the Simple Arithmetic Mean of the comparative prices, 75.1; whereas the erroneously Weighted Mean is 75.7, that is, it is in excess by about .8 per cent. Now the measure of error here predicted by theory⁴ is such that an error of .7 per cent. is as likely as not to occur. The occurrence of .8 per cent. is therefore eminently consonant with the theory.⁵

¹ *Third Report on Depression of Trade*, Appendix B. Memorandum by R. I. Palgrave. Tables 26 and 27.

² Taking 8.5 as the *Modulus* of the resultant error. See above, p. 197.

³ The probability of an error exceeding 1.9 times its modulus is .0072. The probability of the sequence referred to is $.0078 \left(= \frac{1}{2^7} \right)$.

⁴ By case (1) above, p. 11, the modulus is $\frac{1}{\sqrt{n}} \times \sqrt{\frac{SE_r^2}{n}} \times \kappa$. Here n is 19; $\frac{SE_r^2}{n}$

is found to be .08, and κ is .21. Whence the modulus is about .014, or 1.5 per cent.

⁵ Perhaps it may be asked here whether the example given is suited to exemplify our estimate of the *third* species of error (see above, p. 193): that due to the total omission of certain articles. The answer is that this estimate, involving a larger element of induction, does not profess to be so amenable to verification as those which are derived from known and steady 'sources of error,' like our aggregates of

It might be desirable to apply this sort of test on a large scale to the computation recommended by the Committee, and to prove by specific experience the conclusions which are deducible from the Theory of Probabilities concerning the accuracy of any index-number.

These conclusions cannot be stated in their most exact form until the price-returns, as well as the weights which enter into the computation to be tested, are assigned. But even at the present stage of our procedure, and without reference to the price-returns of a particular year, we may approximately estimate the accuracy of index-numbers of the kind proposed by the Committee. For the purpose of a rough estimate it is enough to know the weights (which are assigned in the Second Report of the Committee) and to utilise past experience concerning the course of prices in this country. A certain datum,¹ which had better be determined precisely from the price-returns from the particular year to which the index-number relates, may be approximately obtained by induction from the experience of past years.

Eliciting the required datum from the prices recorded by the *Economist*,² we may provisionally assert the following propositions concerning the accuracy of index-numbers such as the Committee has proposed. These, it will be recollected, involve twenty-seven English price-returns and twenty-seven assigned weights.³

(1) In such an index-number, if the weights alone are supposed subject to error, then the average error of the result, its erroneousness as one may say, is *twenty* times less than the error to which each weight is liable.

(2) If the price-returns alone are liable to error, the erroneousness of the result is about *four-and-a-half* times less than that of each datum.

(3) In the general case, when both prices and weights are liable to error, then, if that error be the same for both species of data, the error of the result is still about *four-and-a-half* times less than that same. If the error of the weights become twice as great as that which is incident to the prices, other things being the same, the error of the result is not materially increased. The error of the weights would need to be *five* times as great as that of the prices in order to increase the error of the result by 50 per cent. (making it only *three* times less than the error incident to the prices alone).

The practical conclusion from these propositions appears to be: Take more care about the prices than the weights.

More detailed statements cannot be made without some assumption as to the degree of inaccuracy to which our data are liable, the extent to which our estimates of weights and prices deviate from the figures which would be assigned if our knowledge and theory were perfect. In entertaining any suppositions as to the extent of this discrepancy, it is proper to conceive that the larger deviations, the more extensive errors, are less frequent in the long run, or more improbable. Thus, if we suppose that a deviation of each datum, weight or price, to the extent of 10 per cent.

digits. Moreover, such verification as the theory admits would require a larger number of items than the table in the text contains. For in general it must be assumed that the numbers both of the included and excluded articles are large. Now it is impossible to carve two sets of 'large numbers' out of *nineteen*.

¹ The coefficient C defined above, p. 191.

² As given in Mr. Palgrave's table 26 (see above, p. 196).

³ Namely, 5, 5, 5, 5; 10, $2\frac{1}{2}$, $7\frac{1}{2}$; $2\frac{1}{2}$, $2\frac{1}{2}$, 9, $2\frac{1}{2}$, 1, $2\frac{1}{2}$; $2\frac{1}{2}$, $2\frac{1}{2}$, $2\frac{1}{2}$, $2\frac{1}{2}$; 10, 5, $2\frac{1}{2}$, $2\frac{1}{2}$;

3, 1, 1, 3, 1, 1. Whence the value of $\frac{Sm_r^2}{(Sn)^2}$ (see above, p. 193) is found to be .05.

is as likely as not, then it may be presumed that a deviation of 20 per cent. is not likely, of 30 per cent. very unlikely. Upon this hypothesis, according to the general formulæ above investigated, the error, or fortuitous deviation from the ideal, to which the Committee's index-number is liable is as likely as not to be as large as 2 or 3 per cent., but is unlikely to be 6 per cent., and very unlikely to be 10 per cent. Now let us entertain the more unfavourable and almost certainly extravagant hypothesis that each datum is as likely as not to be out by 25 per cent., and may just possibly err to the extent of cent. per cent. (an error which, if possible *in excess*, is almost inconceivable *in defect*). Upon this hypothesis our index-number is as likely as not to be out 5 per cent. but is not likely to be out by 10, and very unlikely to be out by 15, per cent.

The presumption that our calculation is not likely to be far out is confirmed by comparing the results obtainable by our method with those obtained by other operators upon different principles. If the compared figures differ little from each other it is presumable that they differ little from the true, the ideally best, figure: that which would be obtained if the data were perfect.

The index-numbers which challenge comparison with that proposed by the Committee may be arranged under four categories, namely:

I. Those which are formed by taking the *Simple Arithmetical Mean* of the given price-variation; the principle of the *Economist's* index-number, or rather what would be the principle of that operation if the prices operated on had not been selected with some reference to the quantity of the corresponding commodities.

II. What may be called the *Weighted Arithmetical Mean*, each price-variation being affected with a factor proportioned to the quantity of the corresponding commodity, the principle adopted by the Committee.

III. The *Geometric Mean*, as employed by Jevons.

IV. The *Median*, proposed by the present writer as appropriate to certain purposes.¹ It is (in its simplest variety) formed by arranging the given price-variation (*e.g.*, 98, 80, 88, 87, 85) in the order of magnitude (*e.g.*, 80, 85, 87, 88, 98) and taking as the Mean the *middle* figure (in the above example the *third* figure, *i.e.*, 87).

Under each of these headings it is desirable to supplement actual verification with *à priori* reasoning based on the principles laid down in the earlier part of the Memorandum.

We may begin with the case (A) in which the price-variations are supposed the same for the compared index-numbers. Later on (B) we shall take examples in which both the price-variations and the mode of combining them are different.

A.

I. Let us take the prices which are to hand for 21 (out of the 27) items of our index-number in Mr. Sauerbeck's well-known paper on the prices of commodities.² Let us form the Simple Arithmetic Mean of these prices for the year 1885, and compare it with the Mean obtained by applying our system of weights to the same prices. The operation is

exhibited in the annexed table, the latter columns of which present a similar comparison for the year 1873. The two results may thus be summed up :

	1885	1873
Simple Arithmetic Mean	70	110·5
The Committee's Weighted Arithmetic Mean	70·6	115

The relation between these results is predictable by, and consilient with, the conclusions of *a priori* reasoning. Accordingly the inference that the deviation between the two computations is not likely to exceed a small percentage may safely be extended to adjacent cases.

It follows, from the principles laid down in the earlier part of this Memorandum, that the discrepancy to be expected between the two results depends on three circumstances: the number of items, the inequality of the price-variations, and the

inequality of the weights. The measure or *modulus* of the discrepancy is, in our notation,

$$\frac{1}{\sqrt{2n}} \times C \times \chi,$$

where n is 21; C is presumed (by a sufficient, but certainly not very copious, induction) to be from .2 to .3; and χ is found to be about .9.¹

It follows that of the observed discrepancies, .6 and .5, one is, *a priori*, more likely than not to occur, and the other not unlikely. A rapidly increasing improbability attaches to the higher degrees of divergence.

Of course it must be understood that this theorem in Probabilities, this statement of what will occur in the long run, is based upon the supposition that the weights are distributed impartially among the price-variations. But if throughout the whole run the largest weight is attached to the largest, or smallest, observation, the then fortuitous character of the phenomenon is impaired. In fact the 'long run' of which the theory may be expected to be true is a series of heterogeneous index-numbers not of consecutive years. Something of this sort is observable in the case of Mr. Palgrave's Weighted Mean compared with the corresponding Simple Arithmetic Mean. The enormous weights attached to the continually low-priced *Cotton* and the continually high-priced *Meat* seem to affect the Weighted Mean abnormally. To effect the comparison, we must not take the averages given in Mr. Palgrave's table 26, but those which are obtained by omitting from that table the three items *Cotton Wool*, *Cotton Yarn*, and *Cotton Cloth*, which do not occur in the compared table 27. The annexed comparison does not present the appearance of pure chance. The discrepancies are rather *less* in magnitude than the theory requires. For the modulus, as deduced from Mr. Palgrave's system of weights, proves to be about 8.5 per cent. of the Mean 80 or 90:² that is about 7, corresponding to a probable error of about 3.5. The set of differences above registered seems to range a little within the limits so defined.

	1870	1871	1872	1873	1874	1875	1876	1877	1878	1879	1880	1881	1882	1883	1884	1885
Mr. Palgrave's Weighted Mean for 19 articles	90	93	100	104	108	97	99	100	95	82	89	93	87	88	80	76
The Simple Arithmetic Mean for the same articles	94	95	102	107.5	107	92	99	101	93	82	93.5	86	89	85.5	81	75
Excess of Arithmetic over Weighted Mean	+4	+2	+2	+3.5	-1	-5	0	+1	-2	0	+4.5	-7	+2	-2.5	+1	-1

The reason is, doubtless, that the impartial sprinkling of the prices among the weights, presupposed by theory, is not fulfilled in fact. Had it happened that

¹ See above, p. 196, where the present writer records the *Mean Square of Deviation* for the price-variation of nineteen different articles (given by the *Economist*) in different years. The *Mean Square of Deviation* for the figures given by Mr. Sauerbeck seems to be much the same. Again, the writer has, with much the same result, ascertained (by the Galton-Quetelet method) the quartiles for a few groups of English prices, like those given by Jevons. For example, in the case of the thirty-nine figures of the prices for prime articles in 1860-62 comparative with 1845-50 (*Currency and Finance*, pp. 51, 52) the quartile (half the interval between the tenth and the thirtieth) proves to be 11, corresponding to a modulus of about 22 per cent. If, however, we take in all the 118 articles given on the same page the quartile is 17. The groups of thirty-nine on Jevons' page 44, so far as they have been examined, give much the same result as the thirty-nine on pages 51, 52. Jevons himself gives $2\frac{1}{2}$ as the 'probable error' incident to the *Mean* of thirty-six price-variations (*Currency and Finance*, p. 157)—corresponding to a probable error of 15, a modulus of 30 for the *individual* price-return. Doubtless the dispersion may be expected to be greater the more distant the base. If precision could be expected, it would be proper to express the coefficient as a percentage of the mean price-variations at each epoch rather than of the initial price or basis.

² See end of last note.

throughout the whole run all the largest weights had been attached to the articles whose prices were continually low, *e.g.*, *cotton*, and (for the last few years at least) *silk* and *flax*, then the discrepancies (between the weighted and simple mean) would have been rather larger than theory predicts. Thus, for the year 1885 I make *silk* exchange weights with *meat*, and thus bring down the index-number to 64; a discrepancy from the Arithmetic Mean which, if continued—as it probably would be—from year to year, would be a little too great. Similarly, when *wheat* exchanges weight with *leather*, and *cotton* with *indigo*, the index-number works out to 92—a discrepancy of two moduli, which is much too large for a continuance.

This sort of abnormality is less likely to occur in the case of our scheme, where none of the weights are so large as some of Mr. Palgrave's. Still, before pressing the theory, it is proper to examine whether the larger weights—in our case those of *meat*, *fish*, and *coal*—are, from year to year, coupled with extreme price-variations.¹

Whenever law of this sort is discernible, the doctrine of Chances hides its inferior light, which is serviceable only in the night of total ignorance. The pure theory of Probabilities must be taken *cum grano* when we are treating concrete problems. The relation between the mathematical reasoning and the numerical facts is very much the same as that which holds between the abstract theory of Economics and the actual industrial world—a varying and undefinable degree of consilience, exaggerated by pedants, ignored by the vulgar, and used by the wise.

II. Next let us compare our result with that obtained by using some other system of weights, *e.g.*, Mr. Sauerbeck's. In the annexed table, page 205, column 1 is the same as column 2 of the last table, containing Mr. Sauerbeck's prices. Column 2 gives Mr. Sauerbeck's weights (for 1885) reduced to percentages of the total weight assigned by him to the twenty-one articles which are common to him and the Committee. For example, 61 is the weight actually assigned by him to wheat. This, multiplied by 100, and divided by 559, the sum of all the weights assigned by him to the twenty-one articles, gives 11 (nearly).

It is an interesting result of theory that the difference to be expected between the two weighted index-numbers (for the same twenty-one price-variations) is about the same as, or only a little less than, that between one of them and the Simple Unweighted Arithmetic Mean. This result is found by putting for $\frac{S\epsilon^2}{n}$ in the formula given above² $\frac{S(\epsilon - \epsilon')^2}{n}$, where ϵ' , ϵ'' , express deviations for the two systems of weights respectively.

	1885	1878
The Committee's System of Weights	70.6	115
Mr. Sauerbeck's System of Weights	73	115

The comparison between the two systems is presented in the accompanying summary. The slightness of the difference between the com-

¹ The effect of large weights combined with high prices is strikingly shown in an index-number (attributed to Dr. Paasche) which is published in Conrad's *Jahrbücher*, vol. xxiii. p. 171. There are twenty-two items, among which *Rye* obtains about thirty per cent. of the total weight, and the Cereals generally (between whose prices there is a certain solidarity) about seventy per cent. It is no wonder that in the year 1868, when the price of the Cereals was exceptionally high, the Weighted Mean should be 118, while the Simple Arithmetic Mean of the twenty-two comparative prices is only 104.

² The expression proves to be equal to .4.

pared results might have been predicted by theory, and may be predicted safely of adjacent cases.

III. We come next to the index-number of Jevons: the Geometric Mean of the price-variations appertaining to a number of groups. The definition of these groups is not wholly irrespective of their importance to the consumer and producer. There is evinced more or less concern that each article of equal importance should 'count for one' in the composition of the index-number. But Jevons does not affect precision of weight. *Pepper*, for instance, forms one of the constituent thirty-nine articles.¹

The analogue of this operation for our materials appears to be the Simple Geometric Mean of the price-variations for each of the articles specified in our scheme; except, indeed, those to which a very small weight, namely 1, has been assigned. Accordingly *Petroleum*, *Indigo*, *Palm Oil*, and *Caoutchouc* may, with propriety, be lumped into one group, for which the mean price-variation is to be ascertained geometrically. For the sake of comparison with Mr. Sauerbeck's result, *Caoutchouc* (not

¹ In the 'Serious Fall,' republished in *Currency and Finance*, p. 44. In the 'Variation of Prices' (*ibid.*, p. 142) Jevons seems to have employed the practice of weighting rather more extensively. He says, 'Several qualities of one commodity have been joined and averaged before being thrown as one unit into larger groups'—in the case of certain articles which are not very clearly indicated. For the period after 1844 the [unweighted] 'average prices, as calculated from the price-lists of the *Economist* . . . were mostly used.'

recorded by him) may be omitted from this little group. The Mean of the group so constituted is to be placed along with the price-variations for the remaining eighteen articles common to us and Mr. Sauerbeck, and the Geometric Mean of all the nineteen is to be taken. It proves to be 69, presenting the comparison herewith exhibited.¹

The Committee's Weighted Mean of 21 articles	70·6
The slightly adjusted Geometrical Mean of the same	69

The slightrness of this divergence is conformable to theory. For it has been shown that the Weighted Mean (of twenty-one articles) is not likely to differ very much from the Simple Arithmetic Mean of the same. And it may be shown that the Arithmetic Mean is not likely to differ very much from the Geometric when the number of price-observations is large, and if they are not very unequal. This proposition may be illustrated by the following figures, the first row of which is obtained by taking the Arithmetic Mean of the thirty-nine price-percentages given by Jevons in his paper on a 'Serious Fall,' &c. (*Currency and Finance*, p. 44.) The second row consists of the Geometric Means, as given by him at p. 46, for the same figures. The superior magnitude of the Arithmetic Mean will be noticed. This circumstance (which Jevons thought an advantage on the side of his procedure) could not be predicated of a *Weighted* Arithmetic Mean (such as our index-number), as compared with the Geometric :—

Geometric Mean for 39 articles	92·4	93·8	111·3	117·6	128·8	116
Arithmetic Mean for same	94·6	94·6	112·4	119	134	119

IV. We come now to the *Median*, which has been recommended by the present writer as the formula for the most objective sort of Mean between prices, not directed to any special purpose, such as the wants of the consumer or the difficulties of the producer, but more impersonal and absolute.

Below 70	Between 70 and 80	Above 80
.	72 72 73 73 77 77 79
Ten below 70	Median = 72	Four above 80

Of the twenty-one price-variations for 1885 given in column 1 of table 1, we have to take that which is the *eleventh* in the order of magnitude. To ascertain this we need not arrange *all* the figures in order. Having an inkling that the Mean is between 70 and 80, we shall find it sufficient to note the number of returns which lie outside those limits, and to write down in the order of magnitude only the returns which lie between 70 and 80. Thus, running our eye down the column of figures, we make a dot on the right for every return which is greater than .80, on the left for every one less than 70; and write down in the central compartment the figures which lie between 70 and 80 inclusive. Whence it

¹ If we lump together *Barley* and *Oats* into one group, *Sugar* and *Tea* into another, and again *Copper* and *Lead*, the Geometric Mean of the sixteen returns thus presented is 70·2.

appears that 72 is the figure eleventh in the order of magnitude: that is the Median.

1	2	3

77	2	2
79	2	1
	12	9
88	3	2
89	2.5	1
94	1.5	1
81	1.5	2
	8.5	6
	36.5	30

This is the Simple or Unweighted Median. There is a variety constituted by assigning special importance to those returns which we have reason to suppose are specially good representatives of the changes affecting the value of money. If, as in the writer's Memorandum often referred to,¹ we take mass of commodity as the principle of ponderation, we shall have to proceed as follows with our twenty-one articles:

As before, make three compartments for returns below 70, for those between 70 and 80, and for those above 80 respectively. Write down in the first and third compartments the returns in the order in which they occur (in any order); but in the central compartment in the order of magnitude.² In the second column of each compartment write the figures representing the relative *precision* assigned to each return. If these estimates of precision are based upon the quantities of commodities, it is recommended that they should be equal to, or rather less than, the square roots of the proportionate masses. Accordingly 2 has been put for the square root of 5, 1.5 for the square root of $2\frac{1}{2}$, and so on. Add together

¹ Sect. ix. of 'Memorandum' in *Report of Brit. Assoc.*, 1887.

² It will probably be convenient to write these returns first in the order of their occurrence, and then rearrange them.

the sums of all the second columns. Thus, $16+12+8\cdot5=36\cdot5$. Find the central figure of the total second column: that is the figure which as nearly as may be has 18 for the sum of figures above it and below it. This figure proves to be the 3 at the top of the second compartment opposite 72. Then 72 is the required Mean.

In the third column another system of precisions has been tried to illustrate the effect of treating some price-variations as more typical of the change in the value of money than others. Tossing up a coin, the writer has stuck down (corresponding to each figure in the first column) 2 if heads turned up, 1 if tails. The sum of these arbitrary coefficients of precision is 30, and accordingly the adjusted Median is the point intermediate between 72 and the return next below in the order of magnitude, which proves to be 67. The adjusted Median is, therefore, $69\cdot5$.

By operating similarly on the price-returns for 1873 (given above) it is found that the Simple Median is 108, the Median adjusted by taking account of quantities still 108.

The deviation between the Median and the Simple (or other) Arithmetic Mean cannot, so far as the writer knows, be formulated exactly. It diminishes with the number of observations, being of the order $\frac{1}{\sqrt{n}}$. A superior limit is given by the expression $\sqrt{1+\frac{1}{2}\pi} \times \text{Modulus of the observation}$; in our case say $\cdot1$, or 10 per cent.¹ This limit is probably very superior, as the following trials, in addition to those given above, suggest :

	1851	1852	1853	1855	1857	1859
Arithmetic Mean for 39 articles .	94·6	94·6	112·4	119	134	119
Median for the same . . .	92	92	108	111	127	116·5
Geometric Mean for the same . .	92·4	93·8	111·3	117·6	128·8	116

The thirty-nine figures are those above referred to, given by Jevons at p. 44 of his *Currency and Finance*. The Geometric Means have been cited again here in order to bring out the curious fact that the Median seems to keep closer to the Geometric than the Arithmetic. This property (which it would be desirable to verify more fully) is agreeable to the theory, first advanced by the present writer so far as he is aware, that prices are apt to group themselves in an unsymmetrical fashion after the pattern of the annexed curve, whose ordinates indicate the frequency of

each price-variation. In the year 1857, for instance, the smallest figure was 91, the largest 247; while the Geometric, Median, and Arithmetic Means were respectively 129, 127, and 134. There is some reason to believe that the Geometric and Median—especially the latter—are more apt to be coincident with the point at which the greatest number of returns cluster, the greatest ordinate of the curve.

If then we take as our quæsitum *that figure which would be presented by the greatest number of price-variations in the complete series of returns*

¹ See the writer's paper in 'Problems in Probabilities,' *Phil. Mag.*, Oct. 1886.

for all articles great and small, then, regarding our twenty-one, or it may be forty-five, articles as *specimens* of this series, we shall best operate on them by taking their Median.

And, even if this reasoning is not accepted, if the asymmetry of the price-curve should not be regarded as serious, and the central point of the supposed symmetrical complete curve or series be taken as the *quæsitum*, still, even upon this hypothesis, the Median would have special claims.¹

Another advantage—or the same otherwise viewed—on the side of the Median is its insensibility to accidental alterations of ‘weight.’ You may considerably increase or lighten the weights without causing this Mean to be depressed or elated. In the Arithmetic Mean a large weight happening to concur with an extreme price-variation produces a derangement which with reference to the present objective² (as distinguished from the ‘consumption’) standard may be regarded as accidental. The Median is free from this fortuitous disturbance. The rationale of this stability is supplied by the Calculus of Probabilities.

It appears, therefore, that our index-number, though not likely to be wide of any mark which has been proposed, is not the one which is most accurately directed to a particular, or rather, indeed, the most general object. It is no matter for surprise or complaint that we should not hit full in the centre an object which has not been our aim; our index-number being mainly a *Standard of Desiderata*, measuring the variation in value of the national consumption. Our primary aim, indeed, is more comprehensive, not this special, but a collective, or ‘compromise,’ scope; not so much to hit a particular bird, but so to shoot among the closely clustered covey as to bring down most game. But then we are brought back to, or nearly to, the directer aim and simpler object by a consideration which has great weight in practical economics, the necessity of adopting a principle—as Mill says with respect to convertible currency—‘intelligible to the most untaught capacity.’ Now every tyro in our subject makes straight for the Consumption Standard; but the more delicate distinctions of the Producers’ Standard and the typical or quasi-objective index-number evade popular perception.

In view of this practical exigency it may well be that the Committee’s index-number is the one best adapted to purposes in general—the principal standard as defined in the First Report. What is here contended is that, with respect to a certain purpose other than the consumers’ interest, the Committee’s index-number is on the one hand likely to be a very good measure, and on the other hand not the very best possible.

B.

We have now to compare index-numbers differing as to the prices operated on as well as the methods of operation. One important case is where the prices of the principal articles are the same for the compared index-numbers, the data differing only as to a small part of the total value. For example, of the total value covered by Mr. Sauerbeck’s index-number about $\frac{9}{10}$ is common to the Committee’s scheme. For Mr. Sauerbeck’s weights (or ‘nominal values’) of the twenty-one articles common to both calculations make up (for the year 1885) 559, while the sum for all the items treated by him is 617.

¹ The problem would then be analogous to the reduction of symmetrical observations relating to a physical quantity. On account of the ‘discordance’ of the price-observations, their very different liability to fluctuation, the writer would recommend the use of the Median on the grounds which he has stated in the paper on ‘Discordant Observations,’ *Phil. Mag.*, April 1886.

² See ‘Memorandum,’ *Report of Brit. Assoc.*, 1887, and also *Journal of the Statistical Society*, June 1888.

Let us see, then, what difference is caused by operating on all Mr. Sauerbeck's forty-five articles instead of only the twenty-one principal items which are common to his price list and ours. He himself at p. 595 (of the ' Journ. Stat. Soc.,' 1886) gives us the Means of Comparison:

	1885	1878
Mr. Sauerbeck's Weighted Mean for 45 articles . .	71·2	115·2
The Committee's Weighted Mean for 21 of those articles	70·6	115

It is interesting to observe that the Median does not suffer any change by being extended from twenty-one to forty-five articles. The attention of the reader is invited also to the ease of this method. In order to take

Above 80	Between 70 and 80.														Below 70
Dots to the number of 12	79	78	77	77	76	75	75	73	73	73	72	72	71	70	Dots to the number of 19

in the twenty-four additional articles we have only to write down a few more figures in the central compartment, to add a few more dots in the extreme compartments, as shown in the annexed diagram. Indeed it is not

1	2	3	1 (continued)	2 (continued)	3 (continued)

71	2	2		2	1
72	1	3		1	2
Sums .	43	47	—	43	47

necessary to record the number of observations (by way of dots) in more than *one* of the extreme compartments. The Median is the *twenty-third* figure in the order of magnitude, that is, 72. Proceeding similarly for the year 1873, we find the Median of Mr. Sauerbeck's forty-five price-variations 109.

Now let us try the effect of weighting. Running my eye over some pages of statistics, I assign the digits 1, 2, 3 as they occur to the price-variations, which are in pell-mell order up to 70; between 70 and 80 in the order of magnitude; and above 80 not represented at all. The sum of the whole second column thus formed is 86. The central point corresponding to half that sum is at the foot of the first half of the second column, corresponding to the entry 72 in the first column. Accordingly 72 is the adjusted Median. I try another system of precision-factors arbitrarily assigned. And still the Median is 72!

The comparisons offered by Mr. Sauerbeck's materials are summed up in the accompanying table :

	1885		1873	
	The 21 articles common to the Committee and Sauerbeck	Sauerbeck's 45 articles	The 21 articles common to the Committee and Sauerbeck	Sauerbeck's 45 articles
The Simple Arithmetic Mean .	70	74	110.5	111
The Committee's Weighted Mean .	70.6	—	115	—
Sauerbeck's Weighted Mean . .	73	72.5	115	115.2
Jevons' adjusted Geometric Mean .	69	—	—	—
The Simple Median	72	72	108	109
The Median adjusted according to <i>quantity</i>	72	—	108	—
The Median adjusted on an arbitrary principle	69.5	72	—	—

For estimating the extent of difference to be expected between two index-numbers which overlap as to some of their items, the following formula is derivable from the reasoning at p. 194. Let n be the number of items common to both schemes, n' the number special to one, and n'' to the other. Put χ'^2 for the fluctuation of one system of weights, and χ''^2 for the other; and for $2 \frac{S(\epsilon' - \epsilon'')^2}{n}$ (above, p. 204) put χ^2 . Then for the modulus of the difference between the compared results we have

$$\frac{1}{\sqrt{n}} \times \sqrt{\frac{\chi^2}{2} + \frac{n'}{n+n'} \left(1 + \frac{\chi'^2}{2}\right) + \frac{n''}{n+n''} \left(1 + \frac{\chi''^2}{2}\right)} \times C;$$

where C , as before, is the measure of the *dispersion* incident to returns of comparative prices. In practice we may put for $\frac{n'}{n+n'}$ the ratio between the summed weights of the item special to each index-number and the sum total for all the items. These fractions are derivable from the third and fourth columns in the last table of the Appendix. In calculating the fifth and sixth columns of that table

the formula just given has been used. But it has been thought allowable to deduce χ not from the Mean *square* of error (as theoretically best), but from the Mean error given in the second column of the table, putting $\chi = \sqrt{\pi} \times$ Mean error. The calculations of χ' and χ'' have been similarly rough.

Of course, as the number of items common to two compared index-numbers is diminished the chances of their dissilience are increased. The *art of conjecturing* can in such a case throw only a very feeble light—offered by the third formula above—on the relation between two such index-numbers. For instance, it could hardly have been predicted that the Simple Arithmetic Mean for Mr. Sauerbeck's forty-five articles should differ so little as .5 from the same Mean for twenty-one articles, as proved to be the case for the year 1873. It is even more surprising that if for 1885 we complete our index-number, taking account of the six items belonging to our scheme not included by Mr. Sauerbeck, there is a marked rise in the index-number owing to all these six returns being above the average. The annexed little table is formed by comparing the prices in 1885 with the average for 1866–77 as given in the *Statistical Abstract*:—

Articles omitted hitherto	Price-variations for 1885	Weight assigned * by the Committee	Product of Columns 2 and 3
1	2	3	4
Fish ¹	104	2½	260
Beer	76	9	68
Spirits ²	120	2½	300
Wine	100	1	100
Tobacco	85	2½	212½
Caoutchouc	109	1	109
Sums	594	18.5	1665
Means	97	—	90

If we add the outcome of this table to that of the first table representing the other twenty-one articles, we have 1665 + 5952 = 7617; which, divided by 100, gives the new index-number 76.

Of course in applying the doctrine of Chances to this problem we must abstract all *animus*. If you pick out the large variations of price and the large weights you will doubtless succeed, like Mr. Forsell, in producing discrepancies—though even his success in that attempt seems less than might have been expected.

In concluding this comparison of results the writer may say, in the phrase of Jevons, that he has taken more than reasonable pains to secure arithmetical accuracy. No doubt mistakes will have come. But, as the calculations have been performed without any conscious bias, any *animus mensurandi*, it may be hoped that the errors will neutralise each other, and that the general impression left by the work is correct.

¹ Fish imported. ² Spirits other than rum and brandy.

APPENDIX.

STATEMENT OF THE EXTENT, AND ESTIMATE OF THE SIGNIFICANCE, OF THE DIFFERENCE BETWEEN THE COMMITTEE'S SCHEME AND OTHERS.

TABLE I.

Articles common to the Committee and Mr. Sauerbeck's Weighted Index-number	Weights actually assigned		Weights as Percentages of Total Weight of the Common Articles		Differences between Columns 4 and 5

Discrepancy very unlikely to occur between the Committee's and other results	8	11	8	8	10	11

Remarks upon the preceding Tables.

These tables present a comparison between the index-number proposed by the Committee and some other well-known constructions of the same kind. In the first five tables the feature of comparison consists of those articles or items which are common to the Committee's and the compared schemes. The tables show the different importance or 'weight' assigned to the same items in the Committee's and each of the other schemes. For the purpose of exhibiting this difference it is proper to contrast, not the actual weights employed by the Committee and each compared index-number, but the weights relative to the total weight assigned to the common items by the Committee's and the compared scheme respectively. Thus, in the first table, the first column states the articles, twenty-one in number, which are common to the Committee's index-number and to one which has been given by Mr. Sauerbeck ('Journ. Stat. Soc.' 1886, p. 595). The second and third columns give the weights actually affixed by the Committee and Mr. Sauerbeck respectively to the comparative prices of those twenty-one articles. The third and fourth columns give the weights relative to the total weight of the coincident portions of the two systems. Thus, 61 being the weight actually assigned by Mr. Sauerbeck to wheat, while 564 is the sum of the weights attached by him to all the articles common to him and the Committee, $\frac{61}{564}$, or the same fraction multiplied by 100 (=11 nearly), is taken as the proper

weight according to Mr. Sauerbeck for wheat; in a curtailed index-number covering only those articles common to him and the Committee. By parity $\frac{5}{81.5} \times 100$, or six nearly, is the weight for the same article according to the Committee. In the sixth column the differences—the absolute differences without regard to *sign*—between the respective weights are given. To appreciate the importance of this difference of weight, we must consider it in relation to the absolute (mean) weight.

Thus $\frac{\text{Mean difference of weight}}{\text{Mean weight}}$ is the fraction (or, multiplied by 100, the

percentage) which most, or at least very, properly measures the discrepancy between the two systems. Now the Mean weight for each of the two compared systems is $\frac{100}{21}$. Therefore we have for the required

measure $\frac{\text{Sum of differences}}{21} \div \frac{100}{21}$, or simply $\frac{\text{Sum of differences}}{100}$ (or, ex-

pressed as a percentage, the sum of differences). Thus in the case before us the average deviation between the compared weights is 46.5, or 47 per cent. (nearly). This figure is useful as enabling us (taking into account the number of common items) to predict the extent of discrepancy which is likely to exist between the results of the two methods of treating the common data.

The second table presents a similar comparison between the Committee's and Mr. Palgrave's index-number ('Third Report of the Committee on Depression of Trade,' Appendix B). It has not been thought necessary to record the actual weights. Those employed in the computation of the 'relative' weights according to Mr. Palgrave were the figures of *comparative importance* given by him for the year 1885, which differ very little from the corresponding entries in previous years. The coefficient of discrepancy between the two systems being much the same as in the former comparison, we may expect much the same difference between the results; or rather one somewhat larger, since the number of common items (sixteen) is here somewhat smaller (than twenty-one).

The remaining index-numbers do not equally admit of being laid alongside that of the Committee for the purpose of comparison. They are as it were in a different plane, adopting a different formula (as well as different constants) from the Committee. In these schemes, unlike the Committee's, each comparative price is not affected with a factor or weight corresponding to its importance. *Primâ facie* every price-variation counts for one; but the principle of weight is to some extent asserted by introducing as independent items several species belonging to one genus. Thus in Mr. Sauerbeck's *unweighted* index-number, our Table 3, there figure *two* species of *wheat* and also one of *flour*; in effect assigning a weight of *three* to *wheat*. There is indeed something arbitrary in such interpretation. For in comparing this sort of index-numbers with the Committee's it is hardly possible—as in the case of the explicitly weighted index-numbers—to suppose the prices (for the common articles) to be the *same* in the two compared calculations. For example, our price of wheat is taken from the 'Gazette'; theirs may be a Mean of that price and the price of flour. Accordingly the estimate of the difference to be expected (proportioned to the total of the last column) is apt to be less accurate, to be under the mark, in these cases. A further inaccuracy affects this estimate in the case of Jevons' index-number, our Table 5, namely, that he adopted the *Geometrical* method of combining price-variations. In fact, our estimates apply only to the *Arithmetic* com-

bination of Jevons' materials, to be supplemented by the observed fact that the Arithmetic and Geometric Means of prices do not much differ.

The last table resumes the results of the first five in its first and second rows. The first row states the number of items common to the Committee with each of the compared schemes—a necessary datum for the estimate of the discrepancy likely to exist between the results. *Cæteris paribus*, this discrepancy is *inversely* proportioned to the *square root* of the number of common items. The second row gives the mean difference between the respective weights as above defined. The third and fourth rows compare the Committee's index-number with each of the others as to the extent of the materials not common to both. The comparison may be thus illustrated. Let CO represent by its length the

quantity of weight common to the Committee and the other index-number. Let CC' represent the total weight of all the articles in the Committee's system, and OO' that of the other system. The third row gives the ratio of CO to CC', and the fourth column the ratio of CO to OO'.

The last two rows give an estimate of the discrepancy likely or unlikely to occur between the results of the compared computations. This estimate involves (in addition to the data contained in the preceding rows) a constant or coefficient deduced from the course of English prices in past years: the inequality or *dispersion* of price-variations, which keeps pretty constant from year to year. The estimates are therefore only applicable to England. They are to be taken *cum grano*, with the reservations stated in various parts of the Memorandum.

Report of the Committee, consisting of Mr. S. BOURNE, Professor F. Y. EDGEWORTH (Secretary), Professor H. S. FOXWELL, Mr. ROBERT GIFFEN, Professor ALFRED MARSHALL, Mr. J. B. MARTIN, Professor J. S. NICHOLSON, and Mr. R. H. INGLIS PALGRAVE, appointed for the purpose of inquiring and reporting as to the Statistical Data available for determining the amount of the Precious Metals in use as Money in the principal Countries, the chief forms in which the Money is employed, and the amount annually used in the Arts. (Drawn up by the Secretary.)

(The bracketed numerals refer to the Remarks appended to the Report.)

UPON the first head of the proposed inquiry the Committee are unable to report favourably. They have not found data available for determining with any degree of precision the amount of gold in use as money in the United Kingdom. Several ways of making an estimate have been indicated by eminent statisticians. But it appears to the Committee that all these computations, as applied to the United Kingdom, fail; owing, not to the incorrectness of the reasoning, but the unsoundness of the data. They remark in detail upon the three methods which appear to deserve most consideration.

I. Newmarch's method, as developed by later statisticians (1), consists of the two following steps:—1. Estimate the amount of precious metal in

circulation at some initial epoch when there has occurred a general or partial recoinage, or other event favourable to the formation of a precise estimate. 2. Add thereto the coin issued from the mint in subsequent years and the coin imported, and subtract the coin withdrawn from circulation as light, the coin exported, and the coin used in the arts.

On this method it may suffice to remark that, as applied to the United Kingdom, it breaks down at the first step. For the only initial datum available is the one which Newmarch employed (2). This is based upon the fact that the light gold in 1843 amounted to 12,000,000*l.*, and the estimate that the light gold formed a third or a fourth part of the total circulation. But this estimate is too rough to permit much confidence in the result, whether 36,000,000*l.* or 49,000,000*l.* as the circulation in 1844.

But, even if that datum were admissible, the reasoning would still be nugatory, failing an estimate of the amount of coin used in the arts during the last forty years, not to insist on the imperfection of statistics relating to the export and import of coin (3).

II. The general idea of Newmarch's method is embodied in a somewhat different scheme, which is largely employed by M. Ottomar Haupt (4). In this second as in the first method we start with the amount of circulation at an initial epoch, and we proceed to add thereto and subtract therefrom. But the mode of estimating the increment and decrement is less direct. The influx and efflux are, so to speak, now observed at a greater distance from the reservoir whose contents it is desired to ascertain. The addendum is now the amount of precious metal imported into (or produced within) the country: not specie only, as before, but also bullion and, we may add, ore (5). The subtrahend is the precious metal exported, together with that which has been consumed in the arts.

The initial datum of this method being the same as for the first method is open to the same objections. And the reasoning built upon that loose foundation is rendered additionally insecure by the proved unsoundness of the statistics which profess to record the exports and imports of precious metal for the United Kingdom (6).

III. There remains Jevons' method (7). His well-known reasoning turns upon two data: 1, the proportion between the number of coins of a certain date which are now in circulation and the total number of coins of all dates which are in circulation; 2, the absolute number of coins bearing the assigned date which are now in circulation, or at any rate a number greater than, a *superior limit* to, the number of those coins.

The first datum appears to admit of being determined with some precision by the inspection of samples taken at random from the circulation. But for the absolute number of the coins bearing an assigned date it seems in general impossible to find a limit which is at once accurate and serviceable. If we take as the limit the number of coins issued from the mint during the assigned period, we are certainly on the safe side. The number of coins issued is indubitably a superior limit to the number of coins circulating. The superior limit to the total circulation which is deduced from this datum may be accepted with peculiar confidence. But this limit is too superior to be of any use for the purpose of making an approximation. Thus Mr. J. B. Martin, operating with the periods 1871-2 and 1876-7 respectively, has found by this method, as superior limits to the circulation of the United Kingdom, the figures 162,803,000*l.* and 182,321,000*l.*! It seems to be obvious, from

the known facts as to the paper circulation of countries which use paper instead of gold, and which are in circumstances otherwise analogous to those of gold-using countries—*e.g.*, Scotland, which uses one-pound notes where sovereigns are used in England—that the above figures as to gold used in England must be greatly exaggerated.

But if we attempt after the manner of Jevons to make corrections for the amount of coin exported, the imperfection of the statistical material recurs upon us with aggravated force (8).

There is added, in the case of the United Kingdom, the special difficulty that the superior limit afforded by the statistics of coinage must be enormously in excess, consisting as it does (for recent years) of the number of coins issued from the mints in Australia as well as the United Kingdom.

Altogether it appears to us that none of these methods can at present afford other than the most vague estimate of the amount of coin circulating in the United Kingdom. With respect to other countries indeed the objections which we insist upon may be less forcible (9).

The Committee have cast about how to remedy the defects which have been noticed (10). The suggestion has been made to reason from the known number of one-pound notes in Scotland to the unknown number of sovereigns in England after this manner. As the volume of transactions in Scotland is to the volume of transactions in England, so is the number of one-pound notes to the number of sovereigns (11). But however good this suggestion may be by way of criticism, and if it is carefully handled, it would not of course be sufficiently trustworthy by itself to yield a conclusion that could be relied on.

The Committee entertain the possibility of making inquiry as to the amount of coin held by different localities or by different classes (12). Such a monetary census would undoubtedly be very incomplete. But if the enumeration, though not exhaustive, were sufficiently impartial and *sporadic*, it seems possible by a cautious and methodical inference from samples to attain a rough estimate (13).

The most that can be expected from the converging lines of inquiry is that three or four very imperfect estimates should be reached by independent methods. The Mean of such estimates—a mean *weighted* according to the presumed trustworthiness of the different sources—appears to be the best result attainable (14). That the best will be imperfect is to be feared.

The second and third inquiries (as to the chief forms in which money is employed and as to the amount of money annually used in the arts) are intimately connected with the first. Accordingly we have thought it best to postpone recommendations under these heads until we have instituted the first investigation more perfectly. To this end, and in view of the extent and difficulty of the subject, we recommend that the Committee should be re-appointed for the ensuing year.

REMARKS.

(1) Mr. Kimbal, Director of the Mint at Washington, and his predecessors have elaborated 'Newmarch's Method.'

(2) See 'History of Prices,' vol. vi. Appendix XXII. There is not much objection to the *method* by which Newmarch obtains the estimate 49,000,000*l.*: namely, deter-

mining the *proportion* of light gold by an inspection of samples taken from the circulation, and multiplying the *quantity* of light gold withdrawn for recoinage by the ratio which the total circulation was found to bear to the light gold. The chief doubt is whether the inspection was made sufficiently carefully. The materials for a more accurate estimate on the occasion of the next recoinage exist in the statistics relative to the state of our coinage obtained by Mr. J. B. Martin ('Journal of the Bankers' Institute,' 1882); supposing them, of course, to be continued up to the date of the recoinage, whenever that may be.

(3) The returns of exported and imported coin published in the Annual Statement of the trade of the United Kingdom do not extend back to the year 1844. There is also the difficulty of estimating the amount of coin in the pockets of travellers; a difficulty which is perhaps peculiarly insuperable in the case of the United Kingdom, owing to the currency of the sovereign on the Continent.

(4) See 'Histoire Monétaire' and 'Währungs-Politik,' by Ottomar Haupt. The distinction between methods I. and II. is well defined by Mr. Kimbal, the Director of the Mint at Washington, in his Report for 1886 (p. 46).

(5) The import of Silver ore into the United Kingdom is not inconsiderable, as pointed out by Mr. Giffen in the First Report of the Committee on Precious Metals.

(6) As pointed out by Dr. Soetbeer ('Materials,' Exports and Imports, Taussig's translation, p. 532), there is a total failure of consilience between the recorded imports of precious metal into England from France and exports from France to England, and *vice versa*. Not even when an average over many years is taken does an appearance of regularity arise (*loc. cit.*). And we may add that if the difference between the efflux from and influx into England—the datum with which we are immediately concerned—be deduced from the English and French statistics respectively, the results are still found to be totally disparate.

The annexed table, compiled from Dr. Soetbeer's *materials* (*loc. cit.*), shows the net influx of gold and silver into England, as deduced from the English and French statistics respectively (000's omitted).

Periods of Years	Net Influx of Gold		Net Influx of Silver	
	English Statistics	French Statistics	English Statistics	French Statistics
1871-75	- 766	- 38,601	- 705	- 48,125
1876-80	- 600	- 55,414	+ 666	- 8,438
1881-84	+ 616	- 2,971	+ 1,506	- 672

On the other hand the returns of the trade in precious metals between the United Kingdom and the United States may inspire some confidence (Soetbeer, *loc. cit.*).

(7) 'Journal of the Statistical Society,' 1868; republished in 'Currency and Finance.' It is as if we should take the census of a population by, 1, ascertaining the ratio between the number of infants, say three years old, and the population of all ages; 2, the actual number of such infants. This absolute number divided by that ratio gives the total population.

A brilliant application of Jevons' method to the statistics of the circulation in France has been made by M. de Foville ('Journal de Statistique de Paris,' 1879 and 1886).

(8) It may well be that the return of exported and imported coin, or rather—what we are concerned with—the difference between these two amounts, is very inaccurate for any single year; but that in a series of years the errors tend to compensate each other. Suppose, for example, that for any single year the estimate of the difference in question is liable to an error of *fifty* per cent.; then the sum of such differences for twenty years—the sort of datum required for our first method—would be liable only to an error of *eleven* per cent. In such a case the first

method might be fairly accurate; while the third method, relying on the exports and imports of a single year (or a biennial period), would be fatally inaccurate.

Moreover, there exists in the third method a difficulty from which the first is free—as to the incidence of the exports for any year on the different strata of the circulation. This difficulty is considered by Mr. Edgeworth in a *Memorandum* on Jevons' method which he has prepared for the British Association.

(9) The careful computations made by Mr. Kimbal, Director of the Mint at Washington ('Reports,' 1886 *et seq.*), inspire confidence. In the case of the United States there is, *first*, a pretty accurate initial datum for the year 1873—on the occasion of the resumption of specie payments. *Secondly*, the statistics of exports and imports are perhaps specially deserving of confidence (cf. above, Remark 6). Mr. Kimbal seems to regard them as satisfactory. *Thirdly*, some attention has been paid to the amount of coin used annually in the arts, though hardly so much attention even yet as to command complete confidence.

(10) It has been suggested by Mr. Edgeworth, in the *Memorandum* above referred to, that Jevons' method may admit of improvement. First, the *ratio* on which the reasoning turns might be determined with greater precision by a more careful and methodical sifting of the data. This correction by itself would not come to much in view of the extreme incorrectness of the other datum (above, Remark 6). But it is further submitted that in some countries the coinage for a particular year or short period may have suffered particularly little from exportation. In fact, something of the sort appears to have occurred in France according to the statistics given by M. de Foville in the papers above referred to.

To revert to the metaphor above employed, the monetary census is effected according to Jevons' method: 1, by ascertaining from samples the proportion of, say, three-year-old infants to the total population; 2, in the absence of accurate data for the number of three-year-old infants now *alive*, the number of infants *born* three years ago. Now suppose, as M. de Foville shows grounds for supposing, that a particular generation escaped in an extraordinary degree the maladies to which infancy is liable; then it might be the best plan to operate, not on infants, as usually taken for granted, but upon that favoured generation, already, perhaps, adult or even superannuated, always supposing that the other datum, the *ratio* determined by sampling, can be ascertained for the favoured generation with adequate precision. But this appears to be doubtful, owing to the circumstance that the generations appearing to enjoy extraordinary longevity consist each of comparatively few individuals. Now a deserved suspicion attaches to the use of *small numbers* in statistics. At any rate, it is not contended that the correction would have any application to the United Kingdom.

(11) In comparing the use of sovereigns in England and one-pound notes in Scotland it would be desirable if possible to make an allowance for the difference which may exist in the use of half-sovereigns in the two countries; and for other differences.

(12) As a specimen of the results which may be attainable, we submit an estimate obtained by Mr. R. H. Inglis Palgrave with respect to a particular town. This town contains about 6,000 inhabitants. It is a railway junction, and also stands upon a river by which seagoing vessels can reach the place. There is also a considerable inland navigation connected with it. The surrounding district is agricultural. The town may be regarded as above the average in prosperity for the agricultural districts. In this town Mr. Palgrave estimates, as the result of investigations set on foot by him, that there would be on an average, taking one time with another, about 4,000*l.* in coin in the hands of the population; that is to say, about 15*s.* a head in gold and silver. This estimate does not include the specie held by the banks. The proportion of gold to silver is about 4:5. Mr. Palgrave is more certain about this proportion than about the absolute amounts. He thinks the latter may be exaggerated, as the country districts surrounding the town are to a certain extent included in the supply of specie mentioned. If this estimate were a fair average it is quite possible that, including the country population referred to in the districts surrounding the town in question, the whole specie in active circulation may not exceed 12*s.*, or even 10*s.*, a head. Further investigation on the point is highly desirable.

(13) Laplace—by a calculation strikingly analogous to Jevons' method above stated—has shown ('Théorie Analytique des Probabilités,' Book II. Chapter VI.) how the method of inference from samples may be used to ascertain the 'population of a great empire.' There is no doubt that this method of reasoning is agreeable to a sound theory of Probabilities, although in incompetent hands it has often produced absurd results. We must guard against proceeding like the statistician mentioned by M. de Foville, who, in order to determine the production of potatoes in France, simply multiplied the production in his own commune by the number of communes in France—with a result out by a hundred per cent.

(14) Supposing the quantity of the circulation as estimated by four different methods of varying trustworthiness were respectively Q_1 , Q_2 , Q_3 , and Q_4 (in ascending order of worth), then the proper Mean might be

$$\frac{Q_1 + 2Q_2 + 3Q_3 + 4Q_4}{1 + 2 + 3 + 4}.$$

MEMORANDUM BY THE SECRETARY ON JEVONS' METHOD OF ASCERTAINING THE NUMBER OF COINS IN CIRCULATION.

PART I.—EXPOSITION.

Jevons' method consists of two stages: (1) the main line of argument, and (2) what may be called a second approximation.

(1) The first step is to ascertain the proportion in the existing circulation of coins bearing each date, or, as¹ Jevons puts it, the number of coins bearing any assigned date, 'now existing in 100,000 [coins] circulating.' This *datum* is obtained by examining a great number of coins taken at random from the circulation.² It is assumed that the proportions in which this collection of samples comprises coins of different dates are approximately identical with the proportions which would be presented if we could examine the whole existing circulation. We have thus:

Total number of coins in circulation : Number of coins of a certain date in circulation :: Total number of samples : Number of samples bearing the assigned date. Whence

Total number of coins = $\frac{\text{Total number of samples}}{\text{Number of samples bearing a certain date}} \times \text{Number of coins of that date in circulation.}$

Now the number of coins of any date now in circulation is *less* than the number of coins of that date issued from the Mint. Whence it follows that the total number of coins in circulation is *less* than

$\frac{\text{Total number of samples}}{\text{Number of samples bearing a certain date issued from the Mint}} \times \text{Number of coins of that date issued from the Mint.}$

We have thus a figure certainly greater than—a 'superior limit' to—the total number of coins in circulation. Or rather we have, or may have, a

¹ *Jour. Stat. Soc.*, 1868, p. 440; *Currency and Finance*, p. 264.

² The principal instances of this operation known to the writer are, for England 165,510 coins (sovereigns and half-sovereigns) examined by Jevons in 1868; 251,107 by Mr. Martin in 1882 (*Journal of the Institute of Bankers*, 1882); by the French Government 2,222,965 coins (of different kinds) examined in 1878, 1,791,808 in 1885 (*Bulletin de Statistique, France*, 1878, 1885); in Belgium, 1878, 103,475 coins by the *Banque Nationale*, 83,599 by the *Ministère des Finances* (*Bulletin de Statistique, France*, 1878). Of the *enquête* said to have been made in France in 1868 the writer has not been able to find any particulars.

great many superior limits, one being afforded by each year (or at any rate each short period¹ of years) as far back as our data reach: in England as far back as 1817, in France 1803.

It remains then to consider which of all these data it is best to employ. Evidently the smallest superior limit will be afforded by the year (or short period) for which the
$$\frac{\text{Number of coins issued}}{\text{Number of coins now in circulation}}$$
 is a minimum;

in other words, that year whose coinage has suffered least loss. Now *à priori* there is a presumption that the coinage which has been longest in circulation will have lost most. And this theoretical conclusion is corroborated by observation. It is shown by Jevons that the 'proportions of coinage surviving' are smaller for the older coinages.² The general truth of the proposition is similarly confirmed by the results of the French *enquêtes*.

It is proper, therefore, to select a recent coinage as that which should enter into the formula above given.³ Accordingly Jevons (writing in 1868) takes the period 1863-4 as his basis. The number of sovereigns coined in that period, 14,578,000l., is to be diminished⁴ by 600,000 known not to have entered into circulation. The remainder, 14,000,000 (nearly), is to be multiplied by $\frac{1,000,000}{1,867,111}$; this being the ratio of the total number of sample sovereigns to the number of samples of sovereigns dated 1863 or 1864. The result is 75,000,000, to which may be added certain sums known not to have entered into circulation, but to be 'lying in bags as received from the Mint' in the Bank of England.

By similar reasoning⁵ De Foville finds, as a superior limit to the number of twenty-franc pieces in France, 175,000,000.

De Foville places this reasoning in a somewhat different shape, or rather in two different shapes. The substantial identity of the various forms may best be contemplated by the aid of symbols. Let E be the required total number of coins in the existing circulation. Put S for the total number of samples, and $s_1, s_2, \dots, s_r, \dots$ for the number of samples bearing date year 1, 2, 3, &c., respectively (the years⁶ being reckoned either onwards from the date of the oldest coin in circulation, or backwards from the most recent period). Let the number of coins issued from the Mint for the corresponding years be $c_1, c_2, \dots, c_r, \dots$. By the reasoning above stated

¹ Owing to the practice which used to prevail of coining with dies which had become out of date, it may not be safe to treat the yearly return as perfectly accurate. See, on the practice alluded to, Jevons, *Currency and Finance*, p. 280; Martin, *Journal of the Institute of Bankers*, 1882, p. 311; De Foville, *Journal de Statistique*, 1886, p. 11.

² *Currency and Finance*, p. 281. Jevons, in the passage referred to, is calculating what may be called the absolute proportion of each coinage surviving; but for our present purpose it is sufficient to know how many times the diminution, or mortality so to speak, of one coinage is greater than that of another. For this purpose we need not suppose, with Jevons in the passage referred to, the total number of coins in circulation to be known. We are concerned here only with the *proportions* between the figures in the second column of Jevons' table at p. 281; and for that part of Jevons' conclusion we do not require the whole of his premisses. We can deduce immediately from the table at p. 264 that part of the table at p. 281 which we here require; namely, that the proportion surviving of coins issued in '63-64 is greater than the corresponding proportion for the period '59-62, and still greater than the proportions for the earlier periods.

³ This general rule and the possible exceptions are illustrated by the diagram on p. 8. The whole matter is placed by De Foville in a clear light (*Journal de Statistique*, 1879, p. 36; 1885, p. 12).

⁴ *Currency and Finance*, p. 265.

⁵ *Journal de Statistique de Paris*, 1878 and 1885.

⁶ Or short periods. See note 2 above.

$E < \frac{S}{s_r} c_r$. One of the forms into which De Foville throws this inequation is $E < \frac{S}{s_r} c_r$. ('Journal de .. Statistique,' 1886, p. 14). Another form (suggested in his paper dated 1879) is $c_1 + \rho_2 c_2 + \rho_3 c_3 + \&c.$; where the years (or short periods) are reckoned backwards from the present, and where $\rho_2, \rho_3, \&c.$, are fractions corresponding to the greater loss which the coinages of early periods, as compared with the most recent, have undergone.

Let e_1, e_2 be the (unknown) number of coins bearing each date in the existing circulation. By hypothesis

$$\frac{E}{S} = \frac{e_1}{s_1} = \frac{e_2}{s_2} \dots = \frac{e_r}{s_r} \quad (1)$$

Also
$$E = e_1 + e_2 + \&c. + e_r \quad (2)$$

$$= \frac{e_1}{c_1} \left[c_1 + c_2 \frac{\frac{e_2}{c_2}}{\frac{e_1}{c_1}} + \&c. + c_r \frac{\frac{e_r}{c_r}}{\frac{e_1}{c_1}} \right]$$

$$= \frac{e_1}{c_1} \left[c_1 + c_2 \frac{\frac{c_1}{e_1}}{\frac{c_2}{e_2}} + \&c. + c_r \frac{\frac{c_1}{e_1}}{\frac{c_r}{e_r}} \right]$$

Now each of the fractions of the form $\frac{\frac{e_1}{c_1}}{\frac{c_r}{e_r}}$ is reducible to $\frac{s_1}{s_r}$; multiplying both the

numerator and denominator by $\frac{E}{S}$ and taking account of equation (1). The factors in this new shape are known quantities derivable from our data. Call them $1, \rho_2, \rho_3 \dots \rho_r$, respectively. Then we have

$$E = \frac{e_1}{c_1} [c_1 + \rho_2 c_2 + \&c. + \rho_r c_r]$$

Whence, as $\frac{e_1}{c_1}$ is a proper fraction (or at any rate not greater than units), we have

$$E < (\text{or at most } =) C_1 + \rho_2 c_2 + \&c. + \rho_r c_r.$$

A geometrical illustration may put the matter in a clearer light. In the annexed diagram the line SS' represents the total number of samples, and its segments $s_1, s_2, \&c.$, the number of samples bearing date 1, 2, 3, &c. The line EE' , divided into the proportionate segments $e_1, e_2, \&c.$, represents the total number of coins in circulation and the numbers thereof bearing each date. The numbers of coins issued from the Mint each year are represented by the lines $c_1, c_2, \&c.$ In general, the more recent the year, the less has the coinage of that year lost, the smaller is the ratio $\frac{c}{e}$. But, as we shall have occasion to remark afterwards, there

may be an exception to this rule, as the figure shows in the case of the year 5.

Now the essence of the reasoning is that $EE' < C_1 C_1'$ (and than any corresponding line, *e.g.*, $C_2 C_2'$). Whether is it easier to say (a) with us, $EE' < \frac{SS'}{s_1} c_1$ or (β) after

De Foville's second redaction (1885) $EE' < SS' \frac{c_1}{s_1}$, or (γ), in the spirit of his first paper, $EE' < c_1 + a_2 + a_3 + \&c.$, where $a_2, a_3, \&c.$, are the remaining segments of the line $C_1 C_1'$. Any of these segments a may thus be expressed in terms of c_r and other known quantities:

¹ $\beta, \beta,$ &c. might be used to designate the 'remaining' segments of $C_2 C_2'$.

$$a = \frac{CC'}{SS'} s_r = c_r \frac{CC'}{SS'} \frac{s_r}{c_r} = c \frac{c_1}{s_1} \frac{s_r}{c_r} = c_r \frac{\frac{c_1}{c}}{\frac{s_r}{s_1}} = \text{say } c \rho.$$

Whence

$$EE' < c_1 + \rho_2 c_2 + \rho_3 c_3 + \&c.$$

(2) Jevons attempts to improve upon the result which has been obtained by means of a second approximation. He seeks a nearer limit to the total number of coins by subtracting from the number of coins issued from the Mint in the most recent period (which forms the datum of the first approximation) a certain proportion which may be known to have been exported.¹ The coinage of 1863–64 forming the basis of his calculation, he ascertains the quantity of coin exported during the short interval of time (1865–67) between the end of that period and the date at which he wrote, which quantity proves to be 8,664,653. He then goes on: ‘There are no means of determining from the above, with accuracy, how much of the coinage of 1863–64 has been exported; but as exporters prefer the newest and heaviest coin, we are probably within the truth in assuming that the sovereigns of 1863–64, which form about one-fifth of the sovereign currency, also form one-fifth of the above exports.’ Accordingly he subtracts from 14,578,000, the number of sovereigns issued from the Mint in 1863–64 (which constituted the uncorrected datum of the simpler² calculation) one-fifth of 8,664,653. He thus succeeds in obtaining a considerably lower limit than by the uncorrected method.

This reasoning admits, or should admit, of being expanded and illustrated as follows. In the annexed figure let the height of each column up to the unbroken

Currency and Finance, p. 267.

² Above, p. 225.

line represent the numbers of coins of each date existing in the circulation at the end of the most recent period designated 1. At that time let exportation act for a short period. Its ravages falling unequally on columns 1, 2, 3, &c., the elevation of

the *broken* lines will represent the new distribution of proportions. Call the new heights h'_1, h'_2 , &c., the old heights being h_1, h_2 , &c. At the beginning of the short period of exportation at least $\frac{h}{Sh}$ of the initial exportation falls upon column 1. At the end of the period at least $\frac{h'}{Sh'}$ of the later drains are taken from that column. Now $\frac{h}{Sh}$ is greater than $\frac{h'}{Sh'}$. Hence for the *whole* period at least $\frac{h'}{Sh'}$ of the total exportation falls upon column 1; $\frac{h'}{Sh'}$ being the proportion of coins dated 1 existing in the circulation at the end of the period of exportation.

It is thus that Jevons argues, or must be supposed to argue: that, as the coinage of 1863-64 constituted in 1868 about one-fifth of the then existing circulation, therefore at least a fifth of the exportation during the period 1865-67 must have fallen upon the coinage of 1863-64.

PART II.—CRITICISM AND CORRECTION.

In criticising this method we may adopt the same order as in expounding it, and separately consider the reasoning which constitutes the first and the second approximation. (1) The fundamental position of the argument is undoubtedly sound, provided that the proportions derived from the inspection of sample collections are sufficiently accurate. For the validity of these data (in the case of one of them at least) we have the high authority of Jevons. 'I feel certain,' he says, 'after drawing up

many averages, that this proportion must be very near the truth.'¹ Still stronger evidence is supplied by the consilience between the results of the French *enquêtes* made in 1878 and 1885. The two curves which represent the proportions in which the circulation in the years 1878 and 1885 respectively comprised coins of each date earlier than 1878 correspond, not only in their general character, but even as to their minuter traits.²

If further accuracy is required, it would be proper to apply the Mathematical Method of Statistics, the doctrine of Errors, to the data. The case is as if we had observed the proportion of males in a great number, say 100,000, births taken at random, so to speak, from the general population. We might suppose a number of subdistricts all over the country selected on some random principle (such as the alphabetical order of their initial letter) and the birth-rate observed for the heterogeneous aggregate thus formed. It is required to determine with what accuracy we can infer, from this aggregate of samples, the proportions prevailing in the total number of births, say 1,000,000, appertaining to the entire population. Suppose that for the aggregate of 100,000 the observed ratio was .51. What extent of deviation from that ratio are the returns for the entire population likely to present?

The proper course would be to break up the aggregate of 100,000 samples into a good number, say 50 (or 25), of smaller parcels consisting each of about 2,000 (or 4,000) units. Let the proportion of male births in each of these small groups be observed. Call these partial ratios r_1, r_2 , &c. . . . r_{50} ; the ratio for the entire aggregate being .51. Form the mean-square-of-error.

$$\frac{(\cdot 51 - r_1)^2 + (\cdot 51 - r_2)^2 + \&c. + (\cdot 51 - r_{50})^2}{50};$$

and put the square-root of double the mean-square-of-error, say μ , for the *modulus*, that constant upon which all the higher operations of the Calculus of Probabilities turn. The modulus for the proportion of male births in a group of 2,000 being μ say .016,³ the modulus for the same ratio in an aggregate of 100,000 births should be $\frac{\mu}{\sqrt{50}}$; or some rather

larger figure which good sense tempering theory may prescribe, say .003. Then we may affirm with confidence that the ratio presented by 100,000 births will not differ from that which would be presented by a much larger number by more than $3 \times .003$; and, therefore, that the proportion of males in 1,000,000 births does not differ from .51 (the observed proportion in 100,000) by more than the calculated limit of error, say .01.

These are not mere anticipations of theory, but practical rules which have been verified by copious experience.

For illustrations of the Theory of Errors applied to statistical reasoning see the writer's 'Methods of Statistics,' *Journal of the Statistical Society*, jubilee vol. 1885, and 'Methods of Ascertaining Rates,' *ibid.* Dec. 1885. It may be observed that in the illustration just given we are not, as in most statistical inductions, inferring from what has been observed of one time or place, to what is true of another time or place; but, from the constitution of samples selected at random to the constitution of the aggregate from which they were taken. The validity of the inference depends upon the impartiality of the selection.

¹ *Currency and Finance*, p. 265.

² See De Foville, *Journal de Statistique*, 1886, p. 12, and *Bulletin de France*, 1885.

³ As may be gathered from the researches of Professor Lexis.

Another illustration may make this point clearer. Suppose that we took 700 hexameters from the 'Æneid,' not *en bloc* from one or two books, as described in the papers referred to, but by a perfectly random process from the whole poem indiscriminately. Suppose (as is likely enough) that these samples being examined should yield the same modulus for the proportion of dactyls as was afforded by the actual specimens examined by the writer: namely .3 (for lines of four feet, the almost unvarying last two feet of the hexameter being left out of account). In this case we may be fairly certain that the proportion of dactyls presented by the sample, say .4, will not differ from the proportion in the whole 'Æneid' by more than $3 \times \frac{.3}{\sqrt{700}}$, say .035. He who carefully considers the verifications adduced

in the second of the papers referred to cannot reasonably doubt this proportion, or, rather, will not feel more than the theoretical degree of uncertainty about it.¹

But when, as in the actual statistics to which reference has been made, the specimens have not been selected with indiscriminate impartiality, then the inductive hazard in inferring from a part to the whole becomes more serious. Even then, however, the inference may be sufficiently safe if inspection has convinced us of the general homogeneity of the total aggregate concerning which we wish to draw a conclusion. The 700 Virgilian lines examined by the writer, though far from being perfect samples, seem still to justify an inference as to the constitution of the whole 'Æneid.' There being in the whole poem some 9,900 lines, it is reasonably certain that a superior limit to number of dactyls in the 'Æneid' is given by the following formula, in which account is taken of the *fifth foot* and of the unfinished lines; whose number we shall call n .

Total number of dactyls in the 'Æneid' is less than

$$4(9900 - n) \left(.4 + 3 \frac{.3}{\sqrt{9900 - n}} \right) + \text{number of dactyls in the } n \text{ unfinished lines} \\ + (9900 - n - \text{number of spondaic lines}).$$

We ought similarly to test the validity of the ratio which constitutes the foundation of the Jevonian argument. We should break up the aggregate of samples into some fifty parcels, observe the ratio for each batch, and thence extricate the necessary coefficient. Of course it would be desirable to employ judgment in testing the worth of our result. We might notice, for instance, whether the modulus derived from one half our samples was much the same as that which the other half yielded. We should observe whether the modulus for batches of 4,000 is as much less as it ought to be than the modulus found for batches of 2,000. Such inspections intelligently performed would suggest to what extent the general rule above exemplified might require some relaxation in view of the specially loose character of our materials.

We shall thus determine the utmost extent of error which we are likely to commit in putting the observed ratio

$$\frac{\text{Number of samples bearing a certain date} \left(\text{say } \frac{s_1}{S} \right)}{\text{Total number of samples}} \\ \text{for the (unknown) ratio} \quad \frac{\text{Number of coins of that date in circulation}}{\text{Total circulation}}.$$

Call this maximum of error (which may be either in excess or defect) λ . By means of this datum we can correct the superior limit (to the circulation) obtained lately.

That superior limit, it may be recollected, was—

$$\frac{\text{Total number of samples}}{\text{Number of samples bearing a certain (recent) date}} \times \text{coins issued}.$$

¹ One source of uncertainty is that the determination of the modulus from a limited number of observations is liable to a certain error.

from the Mint at that date; ¹ in symbols $\frac{S}{s_1} c_1$. But we have now to take account that $\frac{S}{s_1}$ may be too small. It may be as much too small as $\frac{s_1}{S}$ may be too large. The true ratio which $\frac{S}{s_1}$ represents cannot then be larger than $\frac{1}{\frac{S_1}{s} - \lambda}$. That expression, multiplied by c_1 , constitutes a perfectly safe superior limit—comparable to the *safe load* or *breaking load* of mechanical construction.

No doubt a similar degree of evidence might be attained by repeated *enquêtes*, such as those performed by the French Government. The marvellous consilience between most of the ratios yielded by the samples of 1878 and 1885 goes far, as already observed, to establish the accuracy of those ratios. It is, however, desirable, for the purpose of exact computation, to have a *numerical* limit to the possible error of each proportion which we utilise. And, at any rate, it is philosophical not to expend labour in increasing our materials, when the same amount of evidence could be crushed out of a smaller quantity of material by a properly directed scientific process.

Moreover, if this operation be performed, we shall be able, so to speak, to cut the argument much more finely; to obtain a smaller, perhaps much smaller, superior limit than would be safe for the empirical statistician. It will be recollected that a coinage of recent date was selected as the basis of our calculation, because, in general, recent coinages have suffered less loss. But there is some evidence that there are exceptions to this rule. Now, if this evidence were confirmed by rigid application of the mathematical test, we might obtain a much more favourable basis for the calculation than it has hitherto been safe to employ.

The matter is placed in a very clear light by the French statistics, which tabulate for each year the ratio $\frac{\text{Number of samples}}{\text{Number of coins issued}}$ (in De Foville's notation y). Now the expression for the superior limit may, after De Foville, be written

$$\frac{\text{Number of coins issued}}{\text{Number of samples}} \times \text{Total number of samples.}$$

For our purpose, to find the smallest superior limit, the *largest value* of the ratio designated by the French as y would be the best, provided that it is accurate.

De Foville employs a ratio of about $\frac{2}{1000}$; but there occur in the French statistics the entries 7, 12, 17, nay 26 (each to be divided by 1000); and in the Belgian statistics much more startling proportions.

Supposing we were assured that $\frac{4}{1000}$ was a genuine ratio (the coinage of the particular year corresponding having suffered particularly little—a quite reasonable supposition, as De Foville shows), then, the number

¹ See above, p. 225 and p. 227.

of samples being 384,302, for our superior limit we should have $\frac{384,302,000}{4} = 96,000,000$ (pieces of 20-francs) nearly; whereas De Foville has 175,000,000.

(2) We have now to criticise the logic of the 'second approximation' which takes into account the exportations of coin. The reasoning which has been described appears to be formally correct provided that the period during which the exportation is supposed to act is sufficiently small; ideally diminished in the spirit of the differential calculus. But it is a matter of delicacy extending the conclusion to cases in which the 'period' cannot be regarded as infinitesimal. An illustration, Jevons' own, will best exhibit the difficulty. Jevons argues that, as the coinage of 1863-4 constitutes about one-fifth of the existing circulation, therefore at least a fifth of the exportation during the period 1865-7 must have fallen upon the coinage of 1863-4. But how is it known that the main part of the exportation of 1867 (or even 1866) did not fall upon the coinage of 1865?

But it is needless to examine how much the reasoning leaks here, if a more serious gap is caused by the omission of all reference to imported coin. How do we know that the imports during the later portion of the period of 1865-7 did not bring back many of the coins which the exports at the beginning of the period had taken away?

The following correctives are suggested. For a certain period (such as Jevons selected, 1865-7, or shorter) observe *samples* of the exports and imports (opening and examining many outward-bound treasure-chests) and thereby determine the proportion both of the exports and of the imports (for that period) which consists of coins belonging to a certain recent period corresponding to Jevons' 1863-4. Then we may reason thus; placing ourselves in imagination at Jevons' epoch 1868 (or, *mutatis mutandis*, in 1888).

(1) Number of coins dated '63-4 now in circulation = *at most* number of coins issued '63-4 *minus* (proportion of exports '65-7, consisting of coins '63-4) \times (exports '65-7) *plus* (proportion of imports '65-7, consisting of coins '63-4) \times (imports '65-7) *minus* bags in Bank of England, as mentioned by Jevons (and other known items).

(2) (Total number of coins (of all dates) in circulation) \times proportion of coinage '63-4 in existing circulation (found by sample) = number of coins dated '63-4 in circulation.

(3) Total number of coins in circulation is *greater than the right-hand member of equation*, or rather *in-equation* (1), *divided by* proportion of coinage '63-4 in existing circulation.

This reasoning takes for granted that the invisible or unregistered exports are compensated, or at least not exceeded, by the imports of the same species. It must be assumed also—what has been doubted upon good authority¹—that the statistics which we have are fairly accurate. A chink in the logical structure may be filled up; but rottenness of the statistical material is irreparable.

¹ See Soetbeer's *Materialen*, p. 48. It is possible that the conditions necessary for the application of Jevons' method may fail for the United Kingdom, but may be partially fulfilled for some other of the 'principal countries' which are comprehended in our province.

Fourth Report of the Committee, consisting of Dr. E. B. TYLOR, Dr. G. M. DAWSON, General Sir J. H. LEFROY, Dr. DANIEL WILSON, Mr. R. G. HALIBURTON, and Mr. GEORGE W. BLOXAM (Secretary), appointed for the purpose of investigating and publishing reports on the physical characters, languages, and industrial and social condition of the North-Western Tribes of the Dominion of Canada.

THE Committee report that, in addition to Mr. Wilson, of Sault Ste. Marie, who contributes some valuable remarks upon the Sarcee Indians, they have been enabled to secure the services of Dr. Franz Boas (now of New York, and one of the editors of 'Science'), who has been for several years engaged in ethnological investigations in America, particularly among the Eskimo and in British Columbia, and who has consented to return to that province for the purpose of continuing his researches there on behalf of the Committee, and in accordance with the instructions comprised in their 'Circular of Inquiry.' Only eight or nine weeks—in May, June, and July last—were available for his trip, but, with the advantage of the experience and information obtained in his previous journey, he has been able to gather a large mass of valuable material. The results of his inquiries will be given in his final report, to be presented next year. For the present occasion he has prepared some preliminary notes, with an introductory letter (addressed to Mr. Hale), containing a brief account of his proceedings, and some important suggestions concerning future inquiries and the condition of the Indians of that province. The letter is as follows:—

'I beg to transmit the following report of my proceedings, with preliminary notes on the results of my researches in British Columbia. In your instructions dated May 22, 1888, you made it my particular object, on the present trip, to obtain as complete an account as possible of the coast tribes and their languages. As on my previous journey, in the winter of 1886-87, I had collected a considerable amount of material respecting the southern tribes, I turned my attention at once to the Indians inhabiting the northern parts of the coast, including the Tlingit. On June 1 I arrived in Vancouver, and after ascertaining certain doubtful points regarding the Skqomish, who live opposite the city, I proceeded to Victoria on June 3. Mayor J. Grant, of that city, kindly gave me permission to take anthropometric measurements of such Indians as were in gaol. This proved the more valuable, as the natives were very reluctant to have any measurements taken. I sought to obtain measurements and drawings of skulls in private collections in Victoria, and was fortunate enough to be able to measure eighty-eight skulls from various parts of the coast. The results of these measurements must be reserved for the final report. I will mention only the remarkable fact that skulls of closely related tribes show great and constant differences. Comparisons of ten skulls each from Victoria, Sanitch, and Comox give the following results:—

	Length Mill	Length-breadth Index	Length-height Index
Victoria . . .	184.5	77.7	75.0
Sanitch . . .	161.0	95.5	80.8
Comox . . .	176.6	77.9	77.4

These differences are in part due to artificial deformation. It seems, however, that this explanation is not sufficient. These tribes belong to the Salish stock.

‘As soon as an opportunity offered to start northward, I left Victoria and stayed the greater part of June in Port Essington, where I studied the customs and language of the Tsimshian, and obtained notes on the Haida. When returning to Victoria a few Hēiltsuk from Bella Bella were on board the vessel, and I obtained notes on this tribe, which supplement to some extent my former observations. After my return to Victoria I took up the Tlingit and Haida languages, and when several canoes from the west coast of Vancouver Island arrived, that of the Nutka. In the beginning of July, Father J. Nicolai, who is thoroughly conversant with the Nutka language, arrived there from Kayokwaht, and in a number of conversations gave me valuable information regarding the grammar of that language. I obtained information respecting their legends and customs from a few natives, and on July 11 went to the mainland. After staying two days in Lytton I proceeded to Golden and up the Columbia river, in order to devote the rest of the available time to the Kootenay. On July 26 I returned east.

‘The results of my reconnoissance are necessarily fragmentary, as I was not able to devote more than a few days to each tribe. I obtained, however, sufficient material to determine the number of linguistic stocks, and the number of important dialects of those stocks which I visited. The vocabularies which I collected during my former and on the present trip contain from 500 to 1,000 words, and embrace the following languages: Tlingit, Haida, Tsimshian, Kwākiutl (Hēiltsuk and Lekwiltok dialects), Nutka, Salish (Bilqula, Pentlatsh, Comox, Nanaimo, Lkungen, Sishiatl, Skqomish, Ntlakápmuq dialects), and Kootenay. I obtained, also, grammatical notes on all these languages, and texts in some of them.

‘I may be allowed to add a few remarks on future researches on the ethnology of British Columbia. Only among the tribes from Bentinck Arm to Johnson Strait the customs of the natives may be studied uninfluenced by the whites. But here, also, their extinction is only a question of a few years. Catholic missionaries are working successfully among the Nutka; the fishing and lumbering industries bring the natives of the whole coast into closer contact with the whites. In all other parts of the country, except on the upper Skeena, the student is, to a great extent, compelled to collect reports from old people who have witnessed the customs of their fathers, who heard the old myths told over and over again. In the interior of the province even these are few, and it is only with great difficulty that individuals well versed in the history of olden times can be met with. After ten years it will be impossible in this region to obtain any reliable information regarding the customs of the natives in pre-Christian times. Even the languages are decaying since the advent of the whites and on account of the extensive use of Chinook. Young people neither understand the elaborate speeches of old chiefs nor the old songs and legends when properly told. Even the elaborate grammatical rules of these languages are being forgotten. For instance, old Nutka will never form the plural of the verb without reduplication, while young men almost always omit it. Instead of the numerous modi, phrases are used—in short, the languages are decaying rapidly. The study of the anthropological features of these races is also becoming more and more difficult on account of their frequent intermarriages with whites; and the

consequent difficulty of finding full-blood Indians. The once abundant material of old native crania and skeletons lying scattered all over the province is becoming more and more scarce as it decays and the country is being reclaimed.

‘It is nowhere sufficient to study languages alone in order to solve ethnological problems; but in this province the study of a large amount of anthropological material is an absolute necessity on account of the diversity of languages and the great dialectic differences in some of them. The Salish stock in British Columbia, for instance, is spoken in eleven dialects, which are each unintelligible to the speakers of the others. It would be of great importance to study the anthropological features of this race, the northern tribes of which are physically very much like the Kwākiutl.

‘Last of all I mention the antiquities of the province. Valuable relics are destroyed every day. They are turned up by the plough and thrown away: graves and mounds are levelled, shell heaps are used for manuring purposes, cairns are removed. The destruction will be very thorough, as those parts in which relics are found are at the same time those which are the earliest to be reclaimed.

‘For all these reasons an early study of the ethnology of the province must be considered a necessity. In the course of a few years much might be done to preserve the most important facts. The languages might be reduced to writing, the interesting poems and songs that are still afloat might be preserved, we might obtain a complete account of the mythology, and sufficient material for anthropological researches. A few years hence it will be impossible to obtain a great part of the information that may now be gathered at a comparatively slight expense.

‘I cannot close these remarks without adding a few words on the present state of the Coast Indians. It is well known that they have been greatly reduced in numbers since the advent of the whites, and that they are still diminishing. It is also well known that, with few exceptions, they have made no progress whatever. The reasons for these facts are easily understood: the natives become accustomed to products of our manufacture, and in order to purchase them become servants where they have been masters before. At the same time their native industries decay. This process is hastened by the influence of missionaries, who discourage all native arts, as connected with their heathenish customs, without being able to supply anything in their stead. Thus the psychical life of the natives is impoverished, and this, I think, accounts principally for their rapid degradation after their first contact with the whites. The only way to civilise these tribes is clearly shown by Mr. W. Duncan’s success at Metlakahtla. He made the Indians of Metlakahtla a self-sustaining, independent community. Similar results are gradually being obtained in other places, and these results show that the establishment of independent industries on co-operative principles will educate the Indians and make them capable of becoming useful members of the State. The easiest and soundest way to do this is to encourage native industries and arts—fishing and working in wood. At the same time the natives ought to be educated to a more sanitary way of living. This can be attained only by putting energetic medical men in charge of Indian districts. There can be no doubt that an intelligent man, capable of adjusting his argument to the mind of the Indian, would easily induce them to a thorough sanitation. The Indians do not individually give up their old customs, but invariably do so in council. By gaining their confidence, the council

could be easily induced to listen to sound advice. I do not believe that it is too late to save the Indian from utter destruction; and we may still hope that the spectacle of an intelligent race becoming more and more degraded and vanishing from the earth's surface will cease to exert its saddening influence upon the traveller who visits the shores of British Columbia.'

To this letter Dr. Boas adds the following:—

PRELIMINARY NOTES ON THE INDIANS OF BRITISH COLUMBIA.

Although the Indians of the north-west coast of America belong to a great number of linguistic stocks, and although their physical peculiarities suggest that they belong to various races, their customs are so much alike that it is impossible to describe one tribe without having reference to all the others. For this reason it is necessary in a general survey to treat their languages and their physical and ethnographical character separately, although from the standpoint of the psychologist it would seem more desirable to describe each tribe by itself.

The following are the principal races inhabiting the province, including the coast strip of Alaska: 1. the Tinnè (or Tinnèh), who occupy the interior from the extreme north to Quesnelle and Chilcot in the south. 2. The Tlingit, on the coast of Alaska; and the Haida, on Queen Charlotte Islands and the southern part of Prince of Wales Archipelago. 3. The Tsimshian, on Nass and Skeena Rivers and the adjoining islands. 4. The Kwākiutl, from Douglas Channel to the central part of Vancouver Island, excepting the west coast of that island and Dean Inlet and Bentinck Arm. 5. The Nutka, of the west coast of Vancouver Island and Cape Flattery. 6. The Salish, on the south-eastern part of Vancouver Island, on the mainland as far as Quesnelle Lake and Selkirk Range, and on Bentinck Arm. 7. The Kutenai, on Kootenay Lake and River, and on the Upper Columbia.

[Dr. Boas here gives brief notes on the grammatical structure peculiar to each of the six linguistic stocks which he has studied—the Tlingit (and Haida), Tsimshian, Kwākiutl, Nutka, Salish, and Kutenai. It has seemed advisable, however, to defer the publication of these notes until they can appear in fuller form in the final report, where they will be accompanied by the comparative vocabularies and the ethnographical map, and can have the benefit of the author's revision of the proofs.]

In the Indian words comprised in this report the vowels are to be pronounced as in Italian, and the consonants, for the most part, as in English. The letters *k* and *g* represent deep gutturals corresponding to the ordinary *k* *g*. The *h* represents the German *ch* in *ich*. The *q* denotes the sound of the Scotch *ch* in *loch*. By *tl* an exploded *l* is indicated, and by *k'* an exploded *ku*, the *u* pronounced very indistinctly.]

SOCIAL ORGANISATION.

I confine myself, in these preliminary notes, to a brief description of the totemism of these tribes, leaving a more detailed discussion of the prerogatives of the chiefs and of certain families to the final report. Among the Tlingit and Haida we find a great number of crests, which, however,

are divided into two groups—the raven and the wolf among the Tlingit, the raven and the eagle among the Haida. The Tsimshian have four totems, the raven (called K'anha'da), the eagle (Laqski'yek), the wolf (Laqkyebō'), and the bear (Gyispōtue'dā). The Hēiltsuk and their northern neighbours have three totems; the killer (*Delphinus orca*) (Ha'nq'aihtēnoq), the raven (K'ō'ihhtēnoq), and the eagle (Wik'oaqhtēnoq). It is a very remarkable fact that among the other tribes of Kāwkiutl lineage no totemism, in its strict meaning, is found. The tribes enumerated above have the system of relationship in the female line. The child belongs to the mother's crest, and, although the wife follows her husband to his village, the children, when grown up, always return to their mother's tribe. I conclude from the fact that the Kwākiutl, south of Rivers Inlet, have the system of relationship in the male line, or, more properly speaking, in both lines; that the Hēiltsuk adopted their system of totems from the Tsimshian. I have not heard a single tradition to the effect that the gentes consider themselves the descendants of their totem; the Tlingit and Haida, as well as the Tsimshian and Hēiltsuk, have certain traditions referring to ancestors who had encounters with certain spirits or animals who gave them their crests. It is true that the Haida and Tlingit claim to have been created by the raven, but the legend has no reference whatever to the totem. The Kwākiutl and Salish tribes are also divided into gentes, but these are not distinguished by animal totems, but derive their origin each from a man who was sent down from heaven by the deity, and who, in some way or other, obtained his crest from a spirit. These legends are of the same character as the corresponding ones of the Tsimshian. The crest of the family is represented on paintings on the house fronts, on the 'totem posts,' and on tattooings. The latter are probably not used by the Tlingit, while the Haida tattoo breast, back, arms, and legs. The Tsimshian tattoo only the wrists, according to their crest. Tattoo marks are also used by the Nutka. The figures on posts and houses have always a reference to the being encountered by the ancestor, but sometimes also figures of the father's crest are used by the owner, the father having the right to permit his child to use them. The posts do not represent a continuous story, but every figure refers to one tradition. Each gens has also names of its own, which among the Tsimshian must have a reference to the father's gens. Thus, on hearing a name a Tsimshian knows at once to what gens both the bearer and his father belong. Among the Salish and Kwākiutl the child follows, as a rule, the father's gens, but he may also acquire his mother's gens. By marriage he always acquires the prerogatives of his wife's family. It is only here that such prerogatives are connected with the gentes. They refer generally to the use of masks and certain ceremonies of the winter dance, the most important of which is the Hā'mats'a, the man-biter. But the accession to these privileges is not only a right of the young man, it is also his duty to accept them. Among the Salish tribes of the Gulf of Georgia the division into gentes is not as clearly defined as farther north. Here a group of gentes forms a tribe, each gens inhabiting one village. In removing the village from one place to the other they retain the same name, which, however, is not the name of the people, properly speaking, but that of their village. Each gens derives its origin from a single man who descended from heaven, and whose sons and grandsons became the ancestors of the gens, the child always belonging to his father's gens. While among the northern tribes marriages

in the same gens, or phratry, are strictly prohibited, there exists no such law among the Salish.

I have not found any trace of a division into gentes among the Kutonaqa.

MYTHOLOGY.

It is one of the most interesting problems of ethnology to study the development of a system of mythology. On the north-west coast of America this study is the more interesting, as we can show how legends migrated from tribe to tribe. The great hero of the mythology of the northern tribes is the raven, who created daylight, mountains, trees, men. These raven legends have spread very far south, being even known to the Cowitchin of Vancouver Island, and probably still farther south. The hero of the mythology of the southern tribes, on the other hand, is the great wanderer, the son of the deity, who, on his migrations all over the world, transformed men into animals, and animals into men. It appears that this legend, which is known from the mouth of the Columbia to Bella Bella, originated with the Salish tribes; however, we do not know how far it extends inland. Another legend belonging to these tribes has spread far north. It refers to a visit to heaven, and the marriage of a young man to the sun's daughter. Traces of this tale are found among the Tsimshian. The myths of the Kutona'qa and of the Okanagan refer principally to the coyote. I shall proceed to describe briefly the myths of the various tribes, at the same time pointing out their connection among each other.

The Tlingit say that the world was originally swinging to and fro in space. There was something underneath it that was to serve as a rest for the world; the latter approached it, but never succeeded in joining it. All animals tried in vain to fasten the world to it. At last a female spirit, Harishane'kō (=the woman under us), smeared her belly with deer tallow, lay down under the world, and when the latter approached the underworld again the tallow fastened both together. The earth is considered square, the corners pointing north, south, east, and west. In the north there is an enormous hole into which the water of the ocean gushes, and from which it returns, thus causing the tides. There is another idea, to the effect that the world is sharp like a knife's edge, but this seems to be said more in a moral aspect, the meaning being that the road of right doing is narrow; whoever does wrong falls from the road and dies. The earth rests on Harishane'kō, and when the latter moves there is an earthquake. The moon is the sun's husband. There is a chief in heaven called Tahit, the ruler of those who fall in war. These fighting souls produce the aurora. It is worth remarking that this belief is also found among the Eskimo. On the same level with the earth, but outside its borders, is the country of those who died of sickness.

The creation legend of the Tlingit is as follows:—In the beginning there lived a great chief and his sister. The chief killed all his sister's sons as soon as they were born. One day when the woman went to the beach mourning the death of her children, a seagull advised her to swallow three stones. She obeyed, and after a few days gave birth to three boys, the oldest of whom was Yētl, the raven. He wanted to avenge the death of his brothers, and challenged his uncle. The latter tried to drown Yētl by making the waters rise until the whole earth was covered. He kept himself afloat by means of his hat, which grew higher as the waters were

rising. Yētl, however, flew up to the sky, and at last pressed down his uncle's hat, thus drowning his enemy. The waters disappeared again, and then Yētl obtained the sun, which was in possession of a chief, and the fresh water, which was owned by the fabulous K'anū'k'. He made trees and mountains next, and finally tried to create man. First he shaped human figures out of stone and wood, but did not succeed. Then he made man out of grass, and for this reason men are mortal. After this Yētl began to wander all over the world, and in all his further adventures he is described as extremely voracious and greedy.

The mythology of the Haida is substantially the same as that of the Tlingit. The raven is called Yētl by the Kaigani, while on Queen Charlotte Island his name is Qoia. His uncle's name is Nenkyilstla's.

The Tsimshian have also traditions referring to the raven, but he is not considered the creator of men. They consider the Nass River region as their original home, and the Nass language the oldest dialect of the Tsimshian. The origin of men is thus accounted for:—A long time ago a rock and an elder, near the mouth of Nass River, were about to give birth to men. The children of the elder were the first to be born, therefore man is mortal. If the children of the rock had been born first, he would have been immortal. From the rock, however, he received the nails on hands and feet.

The Tsimshian worship the deity in heaven, Leqa', who lives above the sun. The raven myths were evidently imported from some foreign sources, and then the raven was made the descendant of this deity in order to account for his supernatural powers. This legend, which is found from Nass river as far south as the northern portion of Vancouver Island, is substantially as follows:—A chief's wife, who was with child, died and was buried. In the grave she gave birth to a boy, who grew up feeding upon his mother's body. Eventually he was discovered and claimed by the chief, who grew to be very fond of him. The boy used to shoot birds and to skin them. One day he put on a bird's skin and flew up to heaven, where he married the deity's daughter. They had a son, who, when born, dropped from his mother's hand and fell into the ocean. He was found by a chief, and in course of time became Tqēmsem, of whom the same adventures are told which Yētl is said to have accomplished. He appears generally in the shape of the raven.

The flood, of which the Tsimshian also tell, is said to have been sent by heaven as a punishment for the ill-behaviour of man. First, all people, with the exception of a few, were destroyed by a flood, and later on by fire. Before the flood the earth was not as it is now, but there were no mountains and no trees. After the flood Leqa' created these too. The earth is considered to be round, and resting on a pillar that is held by an old woman.

The most important of the Kwākiutl legends is that of the wanderer K'ā'nikila. He is the son of the deity, and descended from heaven to earth, where he was born again of a woman. When he came to be grown up he wandered all over the world, transforming his enemies into animals and making friends with many a mighty chief. Another important legend is that of the mink, Tlē'selakila (meaning the son of the sun), who made a chain of arrows reaching from the sky to the earth, on which he climbed up and visited his father, who let him carry the sun in his stead. When, however, he went too fast, and set the earth on fire, his father cast him into the sea. While the northern tribes of this race

are acquainted with the raven legends, those farther south ascribe all the adventures of the raven to the mink. Another class of legends of the Kwākiutl is of great importance as referring to the spirits of the dances. I will mention in this place that these remarkable dances have evidently originated with the Kwākiutl, although they are at present practised by the Tsimshian and Haida, and by some of the southern tribes. The Tsimshian practise only a few of them, the names of the dances being all of Kwākiutl origin. According to their own statements they were obtained by intermarriage with the Hēiltsuk. The Haida adopted them from the Tsimshian. In all these dances ornaments of cedar bark, dyed red, are used, and it appears that this custom also originated among the Kwākiutl. The most prominent figure of this winter dance is the man-eater, called Hā'mats'a (the eater) by the Kwākiutl, Elaqō'tla by the Bilqula, Ō'lala by the Haida and Tsimshian. The latter call his dance also the Wihalai't (the great dance). The Hā'mats'a is initiated by a spirit, referring to which numerous traditions exist. It is a peculiarity of Kwākiutl mythology that it treats of many supernatural beings, while farther north almost exclusively the heaven, the sun, moon, and raven have supernatural power. Among these beings the following are of importance:—The Tsōnō'k'oa (probably a mythical form of the grizzly bear), the Thunderbird, the Sī'siūtl (the double-headed snake), and a cuttlefish of enormous size. The myths of the Hēiltsuk are much influenced by those of the Bilqula, their eastern neighbours.

The legends of the Nutka treat also principally of the great wanderer, and embody, so far as I am aware, no element which is not found among the Kwākiutl.

The legends of the Salish vary to a great extent among the various tribes, those of the coast tribes resembling the myths of the Kwākiutl. The wanderer and the sun are here the heroes of the greater part of the myths. The legend of the wanderer does not differ from that of the Kwākiutl, except in that he is himself the deity. Each remarkable stone or rock is described as being a man transformed by him. He made a great fire in order to destroy man, and later on made the ocean rise and cover the land. The ascent to heaven on a chain of arrows is one of the principal objects of their legends, the tale treating frequently of a murder of the old sun and the origin of the new one. Besides this, the double-headed snake is of importance, even more so than among the Kwākiutl.

The mythology of the Bilqula, whose language is closely related to that of the dialects of the Gulf of Georgia, differs greatly from that of the other Salish tribes, being evidently influenced by their neighbours. Their mythology, on the other hand, has influenced that of the Hēiltsuk. I do not think that the wanderer legend is found among them. They tell of the raven who created daylight, and of two men, Masmasalā'niq and Yula'timot, who descended from heaven, created man, and gave him his arts. This legend is one of the most beautiful of those found on the coast. Its origin is doubtful. It would be necessary to study the mythology of the tribes of the interior more closely in order to arrive at a satisfactory understanding of this myth. The Bilqula have also the legend of the mink carrying the sun. They call him T'ōtk'oa'ya.

I am not well acquainted with the myths of the tribes of the interior, having collected only a limited number among the Ntlakapamuq. They also tell of the wanderer who transformed men into stones, but it is doubtful whether he is in any way connected with the deity. Their

legends referring to the sun are numerous, one of the most important being the visit to the sun. There are many legends referring to the raven and to the mink, and here for the first time we find the coyote playing an important part in the mythology.

The heroes of the myths of the Kutonāqa are the sun and the coyote. These myths are more closely connected with those of their south-eastern neighbours than with those of the north-west coast Indians. It is, however, of interest to notice that the legend of a chain of arrows reaching up to the sky, and a conquest of the sky, which is so important in the Salish tales, occurs here also. One of the most interesting legends is that of the origin of the sun. The animals tried by turns to act as the sun, but none succeeded. The coyote almost succeeded, but as he made it too hot, and as he told everything he saw going on upon the earth, he was also compelled to give up his place in the sky, and then the two sons of the lynx became sun and moon. Later on, the coyote became the father-in-law of the sun, and many are the tales that refer to his adventures. He plays a part similar to that of the raven in the tales of the Tlingit.

RELIGION, SHAMANISM, MORTUARY CUSTOMS.

A study of mythology and of customs shows that the Indians of this province worshipped principally the sun or the heaven. The Tlingit and Haida pray to the moon, and in praying blow feathers up as an offering. They also pray to mountains, and believe that the animals of their crest protect them, although they are not forbidden to kill them. They believe in the transmigration of souls, the soul of the deceased being born again in a child of the same gens. The souls of animals return in the same way in their young. Sickness is to a great extent ascribed to witchcraft, and it is the duty of the shaman to cure the sick and to find out the witch. The shaman is initiated by acquiring a spirit. Cleanliness is considered as being agreeable to the spirits; therefore the novice must bathe frequently. Great powers are ascribed to people who abstained from sexual intercourse. The dead, except shamans, are burned, and the ashes put up in small boxes. Shamans are buried near the beach, one coffin being deposited on top of the other.

The Tsimshian have a supreme deity called Leqa'. Prayers are frequently not addressed to him directly, but to spirits, the Neqno'q, who convey them to him. Most of the prayers have conventional forms. In praying for clear weather for instance, they say: 'Neqno'q, Neqno'q, chief, chief, have mercy! Look down upon thy people under thee. Pull up thy foot and wipe thy face!' They think that the existence of man is pleasing to the deity, and that he enjoys the smoke rising from their fires. They pray: 'Have mercy upon us! Else there will be nobody to make the smoke rise up to thee. Have pity upon us!' The Tsimshian believe that the dead live in a country similar to our own, and that they are never in want. The dead are buried, but the heart is taken out and buried apart. Chiefs are sometimes burnt, and so are shamans. If a series of deaths occurred in a family, the mourners used to cut off the first joint of the fourth finger, in order to put an end to the misfortunes of their family.

The Kwākiutl worship the sun. It is not quite clear whether they worship K'anikila, the wanderer, besides, or whether they address their prayers only to the sun. Their dances are closely connected with their

religious ideas, particularly the dance Tlok'oola (= something unexpected coming from above), which, in course of time, has partly been adopted by all their neighbours. There are a great number of spirits of this dance, each of which has his own class of shamans, the duties and prerogatives of whom vary according to the character of their genii. The Kwākiutl bury their dead in boxes, which are placed in small houses or on trees. Posts, carved according to the crest of the deceased, are placed in front of the graves. Food is burnt for the dead on the beach. Their mourning ceremonies are very complicated and rigorous.

The Coast Salish worship the sun. They pray to him and are not allowed to take their morning meal until the day is well advanced. The wanderer, called Kumsnō'ōtl by the Comox, Qāls by the Cowitchin and Lkungen, and Qāis by the Skqomish, is also worshipped. They believe that he lives in heaven and loves the good, but punishes the bad. The art of shamanism was bestowed by him upon the first man, who brought it down from heaven.

The Kutonāqa are also sun-worshippers, even more decidedly so than any of the other tribes. They pray to the sun. They offer him a smoke from their pipe before smoking themselves, and sacrifice their eldest children in order to secure prosperity to their families. They believe that the souls of the deceased go towards the east, and will return in course of time with the sun. Occasionally they have great festivals, during which they expect the return of the dead. They have also the custom of cutting off the first joints of the fingers as a sacrifice to the sun. They pierce their breasts and arms with sharp needles and cut off pieces of flesh, which they offer to the sun. It is doubtful whether they practise the sun-dance of their eastern neighbours. The dead are buried, their heads facing the east. It is of interest that the positions of the body after death are considered to be prophetic of future events. The mourners cut their hair and bury it with the deceased. Warriors are buried among trees which are peeled and painted red. Each shaman has his own genius, generally a bird or another animal, which he acquires by fasting in the woods or on the mountains. The shamans are able to speak with the souls of absent or deceased persons, and are skilful jugglers.

Report on the Sarcee Indians, by the Rev. E. F. Wilson.

The Sarcee Indians belong to the great Athabascan or Tinneh stock, to which the Chipewyans, Beavers, Hares, and others in the North-West and, it is said, the Navajoes, in New Mexico, also belong. They were formerly a powerful nation, but are now reduced to a few hundreds. Their reserve, which consists of a fine tract of prairie land, about a hundred square miles in extent, adjoins that of the Blackfeet, in Alberta, a little south of the Canadian Pacific Railway line, and seventy or eighty miles east of the Rocky Mountains. Although friendly and formerly confederate with the Blackfeet, they bear no affinity to that people; they belong to a distinct stock and speak an altogether different language. They are divided into two bands—the Blood Sarcees and the Real Sarcees.

During my visit, which lasted seven days, I had several interviews with their chief, 'Bull's Head,' a tall, powerful man, about sixty years of age; and it was from him and one or two of his leading men that I

gathered most of my information. I found, however, that the Sarcees were not so ready to converse, or to tell either about their language or their history, as were the Blackfeet, whom I visited last summer. Tea and tobacco seemed to be with them the chief desiderata, and except with gifts of this kind it seemed almost impossible to gain anything from them. And after all, even when plied with these commodities, the information they gave was very meagre, and often far from satisfactory. From what little I saw of these people I should be inclined to say that they are of a lower order and inferior in mental capacity to the Blackfeet; I judge this chiefly by the style in which they told their stories and traditions, such as they were, and by their having no elaborated theories as to certain phenomena in nature, about which many other of the Indian tribes have always so much to say.

Chief 'Bull's Head,' in reply to my questions as to their early history, made a great show of oratory, both by voice and gesture, but much of what he said was very childish and confused, and seemed to be scarcely worth the trouble of putting down.

These people call the Blackfeet 'Katce,' the Crees 'Nishinna,' the Sioux 'Kaispa,' and themselves 'Soténnä.' The Indians of their own stock, as I understand, they call 'Tinnätte.' These two last names seem certainly to connect them with the great 'Tinneh' or Athabaskan nation. Sarcee (or rather Sarxi) is the name by which they are called by the Blackfeet.

WHENCE THESE PEOPLE CAME.

'Formerly,' said 'Bull's Head,' 'the Sarcee territory extended from the Rocky Mountains to the Big River (either the Saskatchewan or the Peace River). Our delight was to make corrals for the buffaloes, and to drive them over the cut bank and let them fall. Those were glorious days, when we could mount our swift-footed horses, and ride like the wind after the flying herd; but now the buffalo is gone we hang our heads, we are poor. And then, too, we used to fight those liars, the Crees: we engaged in many a bloody battle, and their bullets pierced our teepees. Thirty battles have I seen. When I was a child the Sarcees were in number like the grass; the Blackfeet and Bloods and Peigans were as nothing in comparison. Battles with the Crees and disease brought in among us by the white man have reduced us to our present pitiable state.'

Another Indian told us how the Sarcees were at one time one people with the Chipewyans, and gave us the myth which accounts for their separation. 'Formerly,' he said, 'we lived in the north country. We were many thousands in number. We were travelling south. It was winter, and we had to cross a big lake on the ice. There was an elk's horn sticking out of the ice. A squaw went and struck the horn with an axe. The elk raised himself from the ice and shook his head. The people were all frightened and ran away. Those that ran toward the north became the Chipewyans, and we who ran toward the south are the "Soténnä" or "Sarcees."'

'The Chipewyans,' said 'Bull's Head,' 'speak our language. It is twenty years since I saw a Chipewyan. We call them "Tcohtin." They live up north, beyond the Big River' (probably the Peace River).

THEIR TRADITIONS, BELIEFS, &c.

'There was a time,' said 'Bull's Head,' 'when there were no lakes. The lakes and rivers were occasioned by the bursting of the belly of the buffalo. It was when the belly of the buffalo burst that the people divided; some went to the north and some to the south. For years and years I have been told that the Creator made all people, and I believe it. I have heard my mother and other old people speak of the days 'when there were no guns and no horses, when our people had only arrows, and had to hunt the buffalo on foot; that must have been a very long time ago.'

The Sarcees have a tradition similar to that of the Blackfeet about men and women being first made separately, and then being brought together through the action of the mythical being 'Napiw.'

They have also a tradition of the flood, which accords in its main features with that of the Ojibways, Crees, and other Canadian tribes. They say that when the world was flooded there were only one man and one woman left, and these two saved themselves on a raft, on which they also collected animals and birds of all sorts. The man sent a beaver down to dive and it brought up a little mud from the bottom, and this the man moulded in his hands to form a new world. At first the world was so small that a little bird could walk round it, but it kept getting bigger and bigger. 'First,' said the narrator, 'our father took up his abode on it, then there were men, then women, then animals, then birds. Our father then created the rivers, the mountains, the trees, and all the things as we now see them.'

When the story was finished I told the narrator that the Ojibway tradition was very much the same as theirs, only that they said it was a *musk-rat* that brought up the earth and not a beaver. Upon this five or six of the men who were squatting around inside the teepee smoking cried, 'Yes, yes! The man has told you lies; it was a musk-rat, it was a musk-rat!'

It seems dubious whether the Sarcees are sun-worshippers; but, like the Blackfeet, they call the sun 'our father,' and the earth 'our mother.' They also engage each summer in the 'sun-dance.' They depend also for guidance in their actions on signs in the sky and on dreams. They think they know when there is going to be a fight by the appearance of the moon. One of their number, named 'Many Swans,' says he is going to have a good crop this year, for he dreamed that a white woman came down from above and asked to see his garden, and he showed his garden to the woman, and it was all green.

'Bull's Head' had no theory to give as to the cause of thunder; he knew that Indians of other tribes said it was a big bird flapping its wings, but his people did not say so; they did not know what it was; neither had they anything to say about an eclipse.

MANNER OF LIVING.

The Sarcee Indians are at present all pagans; they appear to have no liking for the white people, and the white people seem to have little liking for them, and would gladly deprive them of their lands and drive them away farther into the wilderness were they permitted to do so. But the paternal Government, as represented by the Indian Department,

takes care that they are not imposed upon. There is an Indian Agent stationed on their reserve, who twice a week doles out to them the Government rations, consisting of excellent fresh beef and good flour; and there is also a farm instructor, who has charge of the farming stock and implements, and does what he can to induce these warriors and hunters to farm.

They have also residing among them a missionary of the Church of England, who visits them in their teepees, and does his best to collect their little blanketed children to school, giving two Government biscuits to each scholar as a reward for attendance. But the people are evidently averse to all these things, which are being done for their good. Their only idea of the white man seems to be that of a trespassing individual, who has more in his possession than he knows what to do with, and may therefore fairly be preyed upon.

The dress of these people consists, as with other wild Indians, of a breech-clout, a pair of blanket leggings, beaded moccasins, and a blanket thrown loosely, but gracefully, over one or both shoulders. They wear their long black hair in plaits, hanging vertically, one plait on each side of the face, and one or more at the back. Some of them knot their hair on the top of the head; and some, I noticed, wore a coloured handkerchief folded and tied round the temples. This, I believe, is one distinguishing mark of the Navajo Indians in New Mexico. Very often the leggings and moccasins are dispensed with, and the man appears to have nothing on except his grey, white, or coloured blanket. The women wear an ordinary woman's dress of rough make and material, and short in the skirt, next to the skin, leggings and moccasins, and a blanket round the shoulders. Ornaments are worn by both sexes, but chiefly by the men. They consist of brooches and earrings made of steel, necklaces and bracelets made of bright-coloured beads, bones, claws, teeth, and brass wire, and finger-rings, also of brass wire, coiled ten or twelve times, and covering the lower joint of the finger. Every finger of each hand is sometimes covered with these rings. Both men and women paint the upper part of the face with ochre or vermilion. The people live in 'teepees,' conical-shaped lodges, made of poles covered with tent cotton, in the summer, and in low log huts, plastered over with mud, in winter. They depend for their subsistence almost entirely on the rations supplied by Government. They keep numbers of ponies, but seem to make little use of them beyond riding about. They keep no cattle or animals of any kind beyond their ponies and dogs. The latter are savage, and are said to be descendants of the wolf and the coyote, with which animals they still often breed. They seem to have no manufactures; they make no canoes, baskets, &c., but they know how to prepare the hides and skins of the animals they kill, and they make their own clothing, saddles, bows and arrows, and moccasins. Some of the women do very excellent bead-work. Bridles they do not use; a rope or thong fastened to the pony's lower jaw takes the place of a bridle; their whips are a short stout stick, studded with brass nails, and provided with two leathern thongs as lashes at one end, and a loop for the wrist at the other. Their bows are of cherry wood, strung with a leathern thong, and their arrows of the Saskatoon willow, winged with feathers, and pointed with scrap-iron, filed to a sharp point. The shaft of the arrow has four shallow grooves down its entire length.

GAMBLING.

The Sarcees, like most other wild Indians, are inveterate gamblers. They will gamble everything away—ponies, teepees, blankets, leggings, moccasins—till they have nothing left but their breech-clout. In my report of the Blackfeet last year I mentioned the use of a little hoop or wheel for gambling purposes. I find that the Sarcees also use this, and two of them showed me how they play the game. A little piece of board, if procurable, or two or three flattened sticks, laid one on the other, are put for a target, at a distance of eighteen or twenty feet from the starting-point, and the two players then take their places beside each other; one has the little wheel in his left hand, an arrow in his right; the other one has only an arrow. The play is to roll the wheel and to deliver the two arrows simultaneously, all aiming at the mark which has been set up. If the wheel falls over on one of the arrows, it counts so many points, according to the number of beads on the wire spoke of the wheel that touch the arrow. Nothing is counted unless the little wheel falls on one of the arrows. The articles for which they play are valued at so many points each. A blanket is worth, perhaps, ten points, a pony fifty, and so on.

Another method by which these people gamble is as follows: Two men squat side by side on the ground, with a blanket over their knees, and they have some small article, such as two or three brass beads tied together, which they pass from one to another under the blanket; and the other side, which also consists of two persons, has to guess in which hand the article is to be found—very much like our children's 'hunt the whistle.' The Sarcees use also the English playing cards, but it is a game of their own that they play with them. Whoever gets the most cards is the winner.

MATRIMONY.

The Sarcees are polygamous, the men having two, three, or four wives. The time of moving camp is generally looked upon as a propitious time for love-making. The camp is in the form of a ring, with the horses picketed in the centre. Early in the morning the young men drive the horses to a swamp or slough to water them. They are thinking, perhaps, of some young squaw whom they wish to approach, but they are ashamed to speak to her. Then, as soon as all is ready for the move, the chief gives the word, and the callers summon the people to start on the march. The chief goes first and leads the way. Now is the opportunity for the bashful young swains; they drop behind the rest and manage to ride alongside the young women of their choice, and to get a few words into their ears. If the young woman approves the offer, she follows her white sister's example by referring the young man to her parents. If the parents consent, mutual presents are exchanged, such as horses, blankets, &c.; the girl is dressed in her best, and her face painted, and the young man takes her away. A husband can divorce himself from his wife at any time if he pleases, but he has to restore the presents that he received with her, or their equivalent. Girls are often betrothed at ten years of age and married at fourteen. A betrothed girl may not look in a man's face until after her marriage. A man may not meet his mother-in-law; if he chance to touch her accidentally he must give her a present. At a feast among the Blackfeet at which I was present an impatient mother-in-law was standing without and sending messages to the son-in-law within to make haste and leave before all the good things

were done, so that she might come in and get her share; but he sent word back that he was in no hurry. Parents do not often punish their children, but sometimes, in a fit of ill-temper, will beat them cruelly. They are more cruel to their wives than to their children. While I was making these notes a Sarcee woman came into the lodge with her nose cut off; her husband had done it as a punishment for her keeping company with another man.

MEDICINE.

The Sarcees are not considered to be much versed in the use of medicinal roots and herbs; they are much more ready to take the white man's medicine than are their neighbours, the Blackfeet.

Among themselves they depend chiefly on magic and witchcraft for recovery from sickness. There are about a dozen so-called 'medicine-men' in the camp, but most of them are *women*. Chief among them is an old squaw named 'Good Lodge.' They are always highly paid for their services, whether the patient recovers or not. A medicine-man when called in to see a sick person will first make a stone red-hot in the fire, then touch the stone with his finger, and with the same finger press various parts of the patient's body, to ascertain the locality and character of the sickness. Then he will suck the place vigorously and keep spitting the disease (so he pretends) from his mouth. This is accompanied by drum-beating and shaking a rattle. The Sarcees do not bleed or cup, but they blister (often quite efficaciously) by applying the end of a piece of burning touchwood to the affected part. They also use the vapour-bath. To do this a little bower, about three feet high, is made of pliable green sticks, covered over closely with blankets. Several stones are heated red and placed in a small hole in the ground inside the bower; and over these the patient sits in a state of nudity and keeps putting water on the stones, which is supplied to him by an attendant from without. When thoroughly steamed, and almost boiled, he rushes out, and plunges into cold water. This treatment sometimes effects a cure, but more often induces bad results and death. The vapour-bath, as above described, is used very extensively by Indians of many different tribes; some, however, omit the plunge into cold water.

BURIAL CUSTOMS.

I had a good opportunity to investigate the burial customs of these people. Riding across the prairie with a young Englishman who had spent several years in the neighbourhood, we came upon a 'bluff,' or small copse, of fir and poplar trees, covering some two or three acres of ground. We suspected it was a burial-ground, and, dismounting from our horses, entered it. No sooner had we done so than we found ourselves in the midst of the dead—the bodies wound up in blankets and tent-cloth, like mummies, and deposited on scaffolds from six to eight feet from the ground. Four or five of these bodies could be seen from one point, and others became visible as we pushed our way through the tangled underbrush. A little baby's body, wrapped up in cloth, was jammed into the forked branch of a fir-tree about five-and-a-half feet from the ground. The earth was black and boggy and the stench nauseous. Here and there lay the bleached bones and tangled manes of ponies that had been shot when their warrior owners died—the idea being that the equine spirits would accompany the deceased persons to the other world,

and make themselves useful there. Beside each body lay a bundle of earthly goods—blankets, leggings, saddles, &c., also cups, tin pots, kettles, and everything that the spirit of the departed could be supposed to want. Pursuing our explorations we came upon a ‘death teepee.’ I had heard of these, and had often desired to see one. It was just an ordinary teepee, or Indian lodge, made of poles leaning from the edge of a circle, fifteen feet or so in diameter, to a point at the top, and covered with common tent-cloth. The stench was disgusting, and the ground like a cesspool; but I wanted to see all, so we effected an entrance and examined the contents. The old warrior, whoever he may have been, was wrapped up in rotting, sodden blankets, sitting with his back against an ordinary Indian back-rest. We could not see his face, as the blanket covered it, but the top of his scalp was visible and a great bunch of slimy, filthy-looking eagle feathers adorned his head; just behind him hung his leathern quiver, ornamented with a leathern fringe, two feet in length and full of arrows; also his beaded tobacco-pouch; and by his side were a tin basin, a fire-blackened tin pot with a cover, and a large bundle of blankets, clothing, and other effects. I made a hasty sketch of the dismal scene and then retired. We were glad to mount our horses once more and to breathe again the fresh air of the prairie.

PHYSICAL DEVELOPMENT.

The Sarcees do not strike me as so fine or tall a race as the Blackfeet, although one whose measure I here give was of about the same height as the Blackfoot Indian, ‘Boy Chief,’ whom I measured last year. They have remarkably small hands and feet. I traced on paper the hand of a Sarcee Indian named ‘Head above Water.’

Following is the measurement of an adult Sarcee, about thirty years of age, named ‘Many Shields.’

	ft.	in.
1. Height from ground to vertex ¹	5	8 $\frac{1}{4}$
2. " " meatus auditorius	5	3 $\frac{1}{4}$
3. " " chin	4	11 $\frac{1}{4}$
5. " " umbilicus	3	5 $\frac{3}{8}$
7. " " fork	2	8
8. " " knee-cap joint	1	8 $\frac{1}{8}$
11. " " elbow (bent)	3	6 $\frac{1}{2}$
12. " " tip of finger (hanging vertically)	2	2 $\frac{1}{4}$
13. Height—sitting on the ground	2	11 $\frac{1}{4}$
16. Circumference of chest at armpits.	3	0
17. " " mammæ	2	11 $\frac{1}{4}$
18. " " at haunches	2	11 $\frac{1}{2}$
26. Span—outstretched arms	5	8 $\frac{1}{4}$
27. " thumb to middle finger	0	7 $\frac{1}{2}$
28. Length of thumb	0	2 $\frac{1}{2}$
29. " foot	0	9 $\frac{3}{4}$
30. Head—greatest circumference (over glabella)	1	11 $\frac{1}{2}$
31. " arc, root of nose to inion	1	4
32. " " meatus auditorius, over head	1	1 $\frac{3}{4}$
33. " " over glabella to meatus auditorius	1	1
41. " length of face, root of nose to chin	0	5 $\frac{1}{4}$

Hair, eyes, and skin the same as those of the Blackfoot Indian ‘Boy Chief’ (see Report of 1887).

¹ In the measurements of the Blackfoot ‘Boy Chief,’ given in the Report of last year, the ‘height from ground to vertex’ should have been 5 ft. 8 $\frac{3}{4}$ in., instead of 4 ft. 8 $\frac{3}{4}$ in., as printed.

Two or three young Indians tried the strength of their eyesight. They could count the prescribed dots at a distance of 28 feet.

LANGUAGE.

I cannot give as full a report of the Sarcee language as I did of the Blackfoot, for the reason that no one, so far as I could learn, outside the Sarcee tribe has any knowledge of it. The missionary in charge had only arrived a few weeks before, and though he knew the Blackfoot, and through that medium could make himself understood by a few of the people, he knew nothing whatever of Sarcee. We were told that it was an exceedingly difficult language to acquire, and full of gutturals; others said that it had no vowels in it; others that it was like a hen cackling. Under these circumstances it was vain to expect to make out the grammatical rules of the language, but I thought I would do what I could to collect a small vocabulary of words. A few of the people understood Blackfoot, and some few others Cree, and through the medium of these two languages I was able to collect the following Sarcee words and short sentences:—

VOCABULARY.

Pronounce *a* and *ä* as the first and second *a* in larva, *e* as in they, *i* as in pique, *ɪ* as in pick, *o* as in note, *u* as in rule, *ai* as in aisle, *au* as ou in bough, *h* guttural as in *ich* (German), *ŷ* (a sound found also in the Sioux language) pronounced like the Arabic *ghain*, a *ghr* sound; *tc* like *ch* in church, *ñ* like the French nasal *n* in *bon*.

man (or men)	kättini	a big man	kättini tcu

 ni ditcaki lah?
 nitowá.

NOTES ON THE LANGUAGE.

It will be noted in the above vocabulary—

1. That the first, second, and third persons of the personal pronoun appear to be *sinna*, *ninna*, *inila*; when used as possessives with a noun *si* . . . , *ni* . . . , *mā* . . . ; and when governing a verb (e.g., to smoke, see vocab.), *si* . . . , *ni* . . . , *i* It appears, however, from the various verbs given in the vocabulary, that (if correctly obtained) there must be a great variation in the mode of forming the persons; and this, I expect, is due to their belonging to distinct paradigms.

2. The negative appears to be *to* prefixed to the verb. The Blackfeet Indians prefix *mat* to the verb, and follow it by *ats*. Ojibways prefix *kawin*, and end the verb with *si*. The Sioux simply use *shni* after the verb. Crees prefix *nāmā*.

3. The interrogative particle appears to be *kilah*, or *lah* after the verb. Blackfeet express this by *kāt* before the verb and *pa* after it. Ojibways by *nā*, Crees by *tcī*, Sioux by *he*—all after the verb.

4. The numerals in this language are rather puzzling. There appears to be a double set. *Kositá* was given me as 5; yet 15 was *wiltāñmitañ*; and 50 took again the first form, *kositāté*. So with 16: *kostrani* is 6; *wistañmitañ*, 16; *kostrate*, 60. I notice also that the word for 6 seems to be an extension of the word for 3, and the word for 8 an extension of the word for 4. 10 seems to stand alone, the endings for the 'teens' being *mitañ*, which seems to have nothing to do with *kunisnān*. It seems curious also that the 'teen-ending' should be continued through the 'ties'; twenty-one would seem to be expressed in Sarcee as 10+11; but this is merely a surmise of mine, and if I knew more of the language I could probably explain these seeming irregularities. I may mention here, in connection with this, that the Ojibways count 1 to 5 with distinct words, then seem to begin 1, 2 again with the ending *waswi* from 6 to 10. Ojibways and Crees have almost the same words for the numbers 1 to 6, entirely different words for 7, 8, 9, and are nearly the same again for 10 and 20.

5. The plural of the noun appears to be *ika* or *a*. There does not appear to be any distinction made in the plural endings between animate and inanimate objects.

6. There does not appear to be any distinction made in the first person plural of the verb between 'we exclusive of the party addressed' and 'we inclusive.' In these two points (5 and 6) there is a decided divergence from languages of the Algonkin stock, and a leaning towards the Siouan.

7. *Ittra*, *ninna*; it seems, mean—the first, 'father,' or 'my father,' the second 'mother,' or 'my mother,' the possessive pronoun not being used in the first person for nouns of near relationship. This agrees with the Sioux.

8. The adjective follows the noun, the same as in the Sioux.

9. In the foregoing 260 words and sentences I do not recognise one word as similar to any word in any other Indian language with which I am familiar. But I have never before examined any of the 'Tinneh' or Athabascan stock. I might, perhaps, except *ninna*, *ni* . . . , the second person of the pronoun, which is analogous to *niye*, *ni* . . . of the Siouan dialects.

10. The sign of the past tense may be *te*, and of the future *ita* (see *smoke* in vocab.), but of this I cannot be sure.

11. The Sarcees seem to keep their lips parted while speaking, and the accent is generally on the *last* syllable of the word. The language has rather a clicking, 'slishing' sound.

12. In inflecting some of the verbs I have introduced the personal pronouns, but I imagine their presence is not necessary except for emphasis.

Notes by Mr. H. Hale on the foregoing Report.

Mr. Wilson's report on the Sarcees is specially valuable as being the only detailed account we possess of this interesting branch of the great Tinneh or Athabascan family. Some information concerning the tribe has been given incidentally by various writers, including Sir Alexander Mackenzie, Umfreville, and Petitot, but no particular description of the people has been heretofore published. It has been known merely that they spoke a dialect of the Tinneh language, and that they lived in close alliance with the Blackfoot tribes.

The Tinneh family, or stock, has attracted much attention from ethnologists, partly from the peculiar character of its members and partly from its wide diffusion, in which respect, as Mr. H. H. Bancroft has observed, it may be compared with the Aryan and Semitic families of the Old World. It occupies the whole northern portion of the American continent, from Hudson Bay to the Rocky Mountains, except the coasts, which belong to the Eskimo. Tinneh tribes also possess the interior of Alaska and British Columbia. Other scattered bands—Umpquas, Tlatskanais, and Kwalhioquas—are found in Oregon. The Hoopas and some smaller tribes live in Northern California. Thence, spreading eastward, Tinneh tribes, under various designations—Navahoes (or Navajos), Apaches, Lipanes, Pelones, Tontos, and others—are widely diffused over Arizona, New Mexico, Texas, and the northern provinces of the Mexican Republic.

The best account of the Northern Tinneh, east of the Rocky Mountains, is found in the introductory portion of the 'Dictionnaire de la langue Dènè-Dindjié' of the eminent missionary-philologist, the Abbé Petitot, who resided many years among them, and studied their languages, customs, and traditions with much care. In his list of the tribes belonging to this portion of the stock he makes a division styled mountaineers (*Montagnards*), possessing the country on both sides of the Rocky Mountains. The southernmost tribe of this division, on the east side of the mountains, is the Tsa-ttinnè, a name which he renders 'dwellers among the beavers.' The name is derived from *tša*, beaver (which has various other dialectical forms, *tso*, *sa*, *za*, and *so*), and *tinnè* (otherwise *tennè*, *tena*, *atena*, *tunneh*, *dènè*, *danneh*, *dindjié*, &c.), the word for 'man' in the different dialects. M. Petitot describes the Tsa-ttinnè, or 'Beaver Indians,' as comprising two septs—a northern tribe, who hunt along the

Peace River, and a southern, who dwell about the head-waters of the North Saskatchewan, towards the Rocky Mountains. The latter, he says, are the *Sarcis*, who have separated themselves from the northern band. The tribal name of Soténnă, which Mr. Wilson obtained from the Sarcees, is evidently a dialectical variation of M. Petitot's Tsa-ttinnè.

It has been supposed that the separation of the Sarcees from their Tinneh kindred, followed by their union with the Blackfeet, was the result of dissensions among the Tinneh tribes. But the information obtained by Mr. Wilson shows that this idea was not well founded. The separation is now ascribed by the Sarcees to a superstitious panic, but very probably resulted merely from the natural desire of their forefathers to find a better country and climate. Their southward advance brought them in contact with the Blackfeet, with whom they confederated, not against their Tinneh kindred, as had been supposed, but against the Crees, who have from time immemorial been the common enemies of the Tinneh and Blackfoot tribes.

The legend of the deluge, which Mr. Wilson obtained, is given by M. Petitot in a slightly different form, which on some accounts is worthy of notice. In early times, we are told, there was a 'deluge of snow' in September. This was changed to a flood of water by the act of 'the mouse,' an important character in the mythology of some of the Tinneh tribes, being regarded as 'the symbol or genius of death.' He pierced the skin-bag in which 'the heat' was contained, and the snow was forthwith melted. The flood quickly rose above the mountains and drowned the whole human race except one old man, who had foreseen the catastrophe and had vainly warned his neighbours. He had made for himself a large canoe, in which he floated, gathering on it all the animals he met. After a time he ordered several of these animals to dive and seek for earth. These were the beaver, the otter, the musk-rat, and the arctic duck. According to this version of the story, it was neither the beaver nor the musk-rat that brought up the earth, but the duck. This morsel of earth was extended by the breath of the old man, who blew upon it until it became an immense island, on which he placed successively, during six days, all the animals, and finally disembarked himself.

This story is evidently made up from various sources. The skin-bag of heat bitten through by the mouse seems to be a genuine Tinneh invention. The diving of the animals, with the formation of the new earth, is a well-known creation myth of the Algonkin and Iroquois tribes; and the 'six days' are probably a late addition derived from the missionary teachings. An inquirer among the Indian tribes is constantly coming across such composite myths, which require careful study and analysis.

Other observers agree with Mr. Wilson in regarding the Northern Tinneh tribes as inferior in intelligence to the neighbouring Indians of other stocks. This is doubtless a just view. The inferiority, however, would seem to be not from any natural deficiency, but rather the result of the very unfavourable conditions under which the former are condemned to live. Not much can be expected from bands of widely scattered nomads, often famine-stricken, wandering over a barren region, under inclement skies. In better surroundings their good natural endowments become apparent. The Hoopas of California display much intelligence and energy. Mr. Stephen Powers, in his account of the 'Tribes of California,' published by the American Bureau of Ethnology,

speaks of the Hoopas with much admiration, and styles them 'the Romans of Northern California'; he states that they had reduced most of the surrounding tribes to a condition of semi-vassalage. Mr. J. P. Dunn, an able and experienced writer, in his recent work, 'The Massacres of the Mountains,' describes the Navahoes as the most interesting of all the western tribes. They are a peaceful, pastoral, and agricultural people, remarkable for their industry and for their ingenuity in various manufactures. Their women weave excellent blankets, which, he says, 'have been the wonder and admiration of civilised people for many years. They are very thick, and so closely woven that a first-class one is practically water-tight, requiring five or six hours to be soaked through.' They make pottery, and 'have numerous silversmiths, who work cunningly in that metal.' Their women are well treated, are consulted in all bargains, and hold their own property independently. In 1884 the tribe numbered 17,000 souls, cultivated 15,000 acres of land, raised 220,000 bushels of maize and 21,000 bushels of wheat; they had 35,000 horses and 1,000,000 sheep. It has seemed proper to mention these facts as evidence that the Indians who inhabit so large a portion of British America, and whose descendants are probably destined to hold much of it permanently, belong to a stock which, under favouring circumstances, displays a good aptitude for civilisation.

M. Petitot, it should be observed, speaks of the Sarcee language as forming a connecting link between the languages of the northern and southern Tinnah tribes. Mr. Wilson's vocabulary, though taken under many disadvantages, will doubtless be found extensive enough to afford useful data to philologists in classifying the idioms of this important family.

The Committee ask for reappointment, with a renewal of the grant.

Report of the Corresponding Societies Committee, consisting of Mr.

FRANCIS GALTON (*Chairman*), Professor A. W. WILLIAMSON, Sir DOUGLAS GALTON, Professor BOYD DAWKINS, Sir RAWSON RAWSON, Dr. J. G. GARSON, Dr. J. EVANS, Mr. J. HOPKINSON, Professor R. MELDOLA (*Secretary*), Mr. W. WHITAKER, Mr. G. J. SYMONS, General PITT-RIVERS, Mr. W. TOPLEY, Mr. H. G. FORDHAM, and Mr. WILLIAM WHITE.

THE Corresponding Societies Committee of the British Association beg to report to the General Committee that the Conferences of Delegates were held on Thursday, September 1, and Tuesday, September 6, 1887, at 3.30 P.M., in the Court Room of Owens College.

The following Delegates were nominated for the Manchester meeting:—

Mr. Thomas Lister	Barnsley Naturalists' Society.
Rev. H. H. Winwood, M.A., F.G.S.	Bath Natural History and Antiquarian Field Club.
Mr. William Gray, M.R.I.A.	Belfast Naturalists' Field Club.
Mr. W. P. Marshall, M.Inst.C.E.	Birmingham Natural History and Microscopical Society.
Rev. H. W. Crosskey, LL.D., F.G.S.	Birmingham Philosophical Society.
Mr. Sydney Young, D.Sc.	Bristol Naturalists' Society.
Mr. Horace Brown, F.G.S., F.C.S.	Burton-on-Trent Natural History and Archæological Society.

Mr. Alfred O. Walker, F.L.S.	Chester Society of Natural Science.
Rev. J. M. Mello, M.A., F.G.S.	Chesterfield and Midland Counties Institution of Engineers.
Mr. T. Cushing	Croydon Microscopical and Natural History Society.
Mr. J. G. Goodchild, F.G.S. .	Cumberland and Westmorland Association for the Advancement of Literature and Science.
Mr. A. S. Reid, M.A., F.G.S. .	East Kent Natural History Society.
Mr. Ralph Richardson, F.R.S.E.	Edinburgh Geological Society.
Prof. R. Meldola, F.R.S., F.C.S.	Essex Field Club.
Mr. D. Corse Glen, C.E., F.G.S.	Glasgow Geological Society; Glasgow Natural History Society.
Mr. W. C. Crawford, M.A. .	Glasgow Philosophical Society.
Mr. H. George Fordham, F.G.S.	Hertfordshire Natural History Society and Field Club.
Dr. Ogilvie Grant	Inverness Scientific Society and Field Club.
Mr. A. W. Moore, M.A., J.P. .	Isle of Man Natural History and Antiquarian Society.
Mr. F. T. Mott, F.R.G.S. .	Leicester Literary and Philosophical Society.
Mr. R. L. Tapscott	Liverpool Engineering Society.
Mr. G. H. Morton, F.G.S. .	Liverpool Geological Society.
Mr. Eli Sowerbutts	Manchester Geographical Society.
Mr. Mark Stirrup, F.G.S. .	Manchester Geological Society.
Mr. Henry Wilson, M.A. .	Midland Union of Natural History Societies.
Prof. G. A. Lebour, M.A., F.G.S.	North of England Institute of Mining and Mechanical Engineers.
Mr. J. T. Arlidge, A.M., M.D.	North Staffordshire Naturalists' Field Club and Archæological Society.
Mr. Matthew Blair, F.G.S. .	Paisley Philosophical Institution.
Mr. Robert Pullar, F.R.S.E. .	Perthshire Society of Natural Science.
Mr. Hugh R. Mill, D.Sc., F.R.S.E.	Royal Scottish Geographical Society.
Mr. J. W. Davis, F.G.S. .	Yorkshire Geological Society.
Mr. C. P. Hobkirk, F.L.S. .	Yorkshire Naturalists' Union.

At the first meeting of the Conference the chair was taken by Professor W. Boyd Dawkins, F.R.S.; the Corresponding Societies Committee being represented by Dr. J. G. Garson and Professor R. Meldola, F.R.S., Secretary.

The Secretary read the Report of the Corresponding Societies Committee which had been presented to the General Committee of the Association at the meeting on Wednesday, August 31.

The Chairman called upon the Delegates to make any statements respecting the action that had been taken by their Societies with reference to the suggestions put forward last year, and which had been embodied in the Report just read.

Prehistoric Remains Committee.—Mr. J. W. Davis stated that this Committee had been carrying on its work during the past year, and proposed to apply for reappointment. Two reports had been obtained relating to the bronze implements of the East and West Ridings of Yorkshire, and several others had been promised.

Preservation of Stonehenge.—Dr. Garson stated that the resolution which had been submitted last year to the Delegates at the Birmingham Conference¹ had been considered by the Committee of Section H, and having been adopted by it, had been brought before the General Com-

¹ Report for 1887, p. 465.

mittee and accepted. He believed that in consequence of this action negotiations were now going on between the Council of the British Association and the proprietor of these remains.¹

Professor Boyd Dawkins remarked that the state of neglect into which Stonehenge had been allowed to fall had by no means been overstated in the resolution referred to. A person had recently been seen on a ladder chipping off pieces from the horizontal stone of one of the trilithons.

Ancient Monuments Act.—Dr. Garson pointed out that the local Societies could do good service by inducing the proprietors of prehistoric remains to communicate with General Pitt-Rivers, the Inspector of Ancient Monuments, with the object of placing these remains under Government protection. The Chairman urged those Delegates who represented the Northern and especially the Scotch Societies to use their influence in inducing the owners of ancient remains to assist in carrying out the objects of the Act. In reply to a question by Mr. F. T. Mott, as to whether camps and earthworks were to be taken into consideration, he did not think that any Government could be expected to become a landowner to the extent of all the earthworks in the country.

Provincial Museums Committee.—Mr. F. T. Mott stated that this Committee had been engaged during the past year in collecting particulars respecting museums other than those in London. Considerable assistance had been given by the Secretaries of many of the local Societies.

Professor Boyd Dawkins stated that the schedule issued by this Committee was a very difficult one to fill up, and he expressed a hope that something shorter and simpler would be sent out. The Rev. H. Winwood expressed similar views.

Earth Tremors.—Professor Lebour stated that this subject, which he had brought forward at the Conference of Delegates last year at Birmingham, had since taken a more practical shape, and that it now seemed to be time that a Committee of the British Association should be formed for taking the investigation in hand. Through the advocacy of Mr. Symons, who was unable to be present at the Conference, Sections A and G had agreed to recommend the appointment of such a Committee in conjunction with Section C. The work to be done was of a preliminary character, and its object was rather to inquire into the best methods of conducting observations on Earth-Tremors than to actually cause such observations to be made. The North of England Institute of Mining and Mechanical Engineers had, since the Birmingham meeting, carried on a series of seismoscopic observations at Marsden in the county of Durham, and the daily results, extending over several months and compared with a barometric curve, were shown to the meeting in the form of a diagram by Mr. Walton Brown, the Secretary of the Newcastle Institute Committee. The Institute possessed also a more elaborate instrument, made after a pattern supplied by Professor Ewing, which registered the intensity and direction of the tremors. He stated that, although such instruments as the last mentioned were probably too costly to be placed at all desirable stations, this would not be the case with the simpler seismoscope, which recorded merely the fact of earth-tremors having taken place and the time of their occurrence. Such records would be valuable though limited. The Corresponding Societies, if they would interest themselves in the matter, might be the means of establish-

¹ Report for 1887, p. lxxv.

ing a great network of seismoscopes with a few seismographs in suitable localities, and results of value would by this means be, in all probability, obtained. These results would be valuable in proportion as well-equipped seismometrical observing stations were numerous. The expense must in any case be considerable in the aggregate, but need not be great in individual cases. A sufficiently good seismoscope might be had for about 2*l.*, a seismograph for 14*l.* to 15*l.*, and the cost of keeping them in order would not be great. He hoped the Delegates present would help in establishing such a network of observing stations all over the country, and he would be happy to communicate with anyone interested in the subject.

Professor Ewing, in response to the Chairman, said that from his experience of earth-tremor observations in Japan he could concur in the remarks of Professor Lebour. To investigate fully the character of the motion, even at one station, required delicate and costly apparatus, and the cost was greatly increased when it was attempted to bring a number of stations into correspondence so as to determine the motion over a large area. It was possible, however, to record the fact that a tremor had occurred, and even to learn something of its character by means of inexpensive seismoscopes; and it certainly seemed to him that no bodies could more appropriately undertake that work than the local Societies represented at the Conference acting in conjunction with a Committee of the Association. From recent observations it appeared probable that tremors would be found wherever they were tested for with sufficient delicacy, so that a Society undertaking the search was not likely to be disappointed.

At the second Conference the chair was taken by Professor Boyd Dawkins, F.R.S., who was succeeded by Mr. W. Topley, F.G.S., the Corresponding Societies Committee being further represented by Mr. G. J. Symons, F.R.S., Dr. Garson, Mr. William White, and Professor R. Meldola, F.R.S., Secretary.

The Chairman invited discussion on the recommendations received from the various Sections.

SECTION A.

Temperature Variation in Lakes, Rivers, and Estuaries.—The following resolution was forwarded to the Secretary of the Conference by the Secretary of this Section:—

‘That Mr. John Murray, Professor Chrystal, Dr. A. Buchan, Rev. C. J. Steward, Hon. R. Abercromby, Mr. J. Y. Buchanan, Mr. David Cunningham, Mr. Isaac Roberts, Dr. H. R. Mill, and Professor Fitzgerald be appointed a Committee to arrange for an investigation of the seasonal variations of temperature in lakes, rivers, and estuaries in various parts of the United Kingdom in co-operation with the local Societies represented at the Association; and that Mr. John Murray be Secretary.’

Dr. H. R. Mill, as representing this Committee, stated that the question proposed had not been fully worked out, but that the few observations made showed relations of a very interesting kind. As a branch of meteorology, this research was particularly promising, and was one in which the co-operation of local Societies would be valuable. He proposed that the Societies situated in the neighbourhood of rivers and estuaries which were willing to undertake this work should appoint some

member to observe the temperature daily or weekly, as the case might be, in accordance with the rules to be drawn up by the Committee. It was first proposed to ascertain how many observers would offer themselves in various parts of the country, then to draw up a scheme of observations and arrange for this being adopted.

Mr. G. J. Symons pointed out the necessity in such observations for having a well-considered scheme drawn up, as well as for having absolutely reliable thermometers, without which no observations would be of value. He also asked whether it was proposed that the cost of the instruments should be met by a grant from the British Association, or whether the Societies taking part in the observations should provide their own thermometers.

Mr. De Rance remarked that in the case of the Committee which had been formed for the observation of underground temperatures, and of which Professor Lebour was a member, the thermometers had been supplied by the Association.

Mr. J. W. Davis raised the question as to whether it would be of use to extend the observations to the streams in manufacturing districts. He also asked what the Committee proposed to consider as an estuary.

The Rev. H. Winwood remarked that it would be necessary in all cases to record the depth at which the thermometer-reading was taken. As a point of interest bearing upon the proposed observations, he stated that it had been observed that the temperature of the lakes in the Hebrides had been unusually high this year.

Professor Lebour stated that the thermometers used by the Underground Temperature Committee had been supplied by the Association, but these instruments were very costly, and only a few observers had taken part in the work. He was of opinion that if numerous Societies took part in the observations, these should in each case bear the expense.

Dr. Garson expressed a hope that the temperatures would be recorded on the Centigrade scale.

Dr. Mill, in reply, said that he understood that the fact of the investigation being sanctioned by a Committee of Section A was a sufficient guarantee that it should be carried out in a thoroughly scientific manner with properly verified instruments of a uniform pattern, and employed in the same way. The experience of the Scottish Marine Station for three years suggested many precautions which should be adopted in this work. The temperature of streams in manufacturing districts should certainly be ascertained in as many cases as possible, in order to find whether the increase of temperature of a river passing through a manufacturing town is in any sense permanent. The term 'estuary' should, in his opinion, be used as meaning all parts of a tidal river between the upper limit of the tide and the open sea. Each local Society should be asked to supply its own thermometers, but all these should be verified at Kew, or compared by some person appointed by the Committee. The observations would, of course, be made on a uniform plan, and it would, probably, be found more convenient to use the Fahrenheit than the Centigrade scale, but the readings could be easily converted, if necessary.

Earth Tremor Committee — See under Section C.

SECTION B.

No recommendations forwarded or suggestions made.

SECTION C.

Mr. C. E. De Rance, who represented this Section, referred to the work of the three Committees which he had brought under the notice of the Delegates on former occasions, viz.: (1) The Underground Water Committee; (2) The Erratic Blocks Committee; and (3) The Sea Coasts Erosion Committee.¹

The first of these Committees requires information as to the depth of wells, the sections passed through, the height at which the water stands before and after pumping, daily records of the height and chemical analyses of the waters.

The *Erratic Blocks Committee* wants information as to the position, size, and character of boulders of foreign origin that may occur in drift-covered areas, and is anxious that the position of the same should be noted on the one-inch map of the Ordnance Survey.*

The *Sea-Coasts Erosion Committee*, like the other two Committees, has a printed form of inquiry, which can be obtained on application to Mr. Topley.

With reference to the work of this last Committee, Mr. Topley stated that but little assistance had as yet been received from the local Societies. The Natural History Society of the Isle of Man had undertaken to collect information; and all similar Societies in maritime counties might greatly assist the Committee by local observation as to present changes, and by researches as to past conditions of the coast.

With respect to the work of the Erratic Blocks Committee, Professor Meldola said that he had been authorised to state on behalf of the Manchester Geological Society that several members of that Society had been interesting themselves in the distribution of boulders in their district, and it was expected that their results would be available by the next meeting of the Association. It was also mentioned that Mr. Adamson had been rendering assistance to this Committee on behalf of the Yorkshire Naturalists' Union.

Mr. Ralph Richardson, as the representative of the Edinburgh Geological Society, pointed out that Scotland had been omitted from the localities dealt with by the Erratic Blocks Committee. He stated that much work in this field had already been carried out under the auspices of the Royal Society of Edinburgh, and he hoped the Committee would be able to utilise their results.

Earth-Tremor Committee.—Professor Lebour stated that since the last meeting of the Conference the formation of a joint committee by Sections A, C, and G had been agreed to, and the resolution forwarded to the Committee of Recommendations. The resolution was the following:—

‘That Sir F. J. Bramwell, Mr. E. A. Cowper, Mr. G. J. Symons, Professor G. H. Darwin, Professor Ewing, Mr. Isaac Roberts, Mr. Thomas Gray, Dr. John Evans, Professor Lebour, Professor Prestwich, Professor Hull, Professor Meldola, and Professor Judd be a Committee for the purpose of considering the advisability and possibility of establishing in other parts of the country observations upon the prevalence of earth-tremors, similar to those now being made in Durham in connection with coal-mine explosions, and that Professor G. A. Lebour be the Secretary.’

Mr. De Rance remarked that the proposed observations might possibly

¹ Report for 1887, p. 462.

under certain circumstances become connected with the work of the Underground Water Committee. Thus the Essex earthquake of April 22, 1884, had caused a rise in the level of the water in Messrs. Courtauld's well at Bocking, which had reached its maximum in June of the same year. Since then the level had been gradually falling, and at its present rate it might be expected that the water would be at the same level as it was before the earthquake about next August.

SECTION D.

Life Histories of Plants.—Professor Meldola said that during a recent visit to Oxford he had had an opportunity of hearing a suggestion in the course of a conversation with Professor Bayley Balfour, which had appeared to him as likely to be of use to the members of local Societies. He had therefore invited Professor Balfour to attend the Conference and explain his views on the suggested subject, but as that gentleman was prevented from being present he had forwarded the following communication:—

‘It appears to me that much good scientific work might be done by members of local Societies in a direction which has not attracted so much attention in Great Britain as it deserves. The discovery and description of new forms, and the distribution of our indigenous plants is in Botany the line upon which most of the energies of local Societies are principally spent, whilst habit, construction, and generally the features of life-history of plants come in for attention in quite a secondary way. This arises, I think, in great part from the prevalent notion that the facts of the life-history of our common plants are all well known, and that there is little, if anything, more to find out about them. That this is an erroneous idea may easily be shown—witness, for example, the interesting observations recently published by Sir John Lubbock—and there is a field for a great deal of sound work upon plants growing at our doors.

‘Within recent years Mr. Darwin's work, followed up by that of such men as Hermann Müller, Kerner, Ogle, and others, has given a stimulus to observations of adaptations between the vegetable and animal kingdoms in connection with pollination in flowers; and many interesting facts about British plants have been brought to light by workers in local Societies. But little has been done for the subject of the vegetative organs of these plants—I mean the arrangement, true nature, and structure of the members that carry on plant-life. In Germany many years ago Wydler and Irmisch published a splendid series of contributions to the knowledge of these features in indigenous German plants—why has this not been done for Britain?

‘Now I venture to think that good results would follow if you would bring before the Delegates at the meeting to-day the importance of encouraging the members of their Societies to study the life-histories of indigenous plants in their entirety, *i.e.*, from the stage of embryo in the seed up to the production of fruit and seed again. Anyone who will take up this line of study will assuredly derive great pleasure from it, and will be able to add a great deal to the sum of our knowledge of plant-life. Such work can be well combined with the more usual systematic work, it can be easily accomplished, and it will be found to give much additional interest to the study of British Botany.’

Mr. C. P. Hobkirk considered that Professor Balfour's letter was a very important one, and that, as therein suggested, the time and energies

of the members of local Societies would be far more usefully employed by following the lines indicated by Professor Balfour than, as at present, in simply collecting, naming, and registering local plants. As far as he was concerned, he was prepared personally, and also on behalf of the Yorkshire Naturalists' Union which he represented, to do everything in his power to assist in carrying out practically Professor Balfour's most useful proposition. Although the compilation of local floras was most useful and necessary work, yet the actual life-history of individual forms was now of really paramount importance, and members of local Societies should be urgently requested to carry on this work without delay.

SECTIONS E and F.

No recommendations forwarded or suggestions made.

SECTION G.

Earth-Tremor Committee.—See under Section C.

SECTION H.

Ancient Monuments Act.—The Secretary read the following communication from General Pitt-Rivers:—

'I am much afraid I shall not be able to be present at the meeting of Delegates of local Societies on Tuesday; but the subject is so important for the preservation of these monuments that, in case I am not there, I write in order that you may know what my view of the matter is.

'Perhaps I cannot do better than state in a few words what the work of the Inspector of Ancient Monuments is, and you will then see what kind of progress is likely to be made without some assistance such as has been proposed,¹ and in what way the assistance of local Societies can be given.

'You are probably aware that, in the original Act of 1882, fifty ancient monuments in Great Britain were scheduled as monuments to which the Act could apply at once if the owners were willing. Some persons suppose that by scheduling these monuments they were actually placed under the Act, but this is not the case. The scheduling was done without the knowledge or consent of the owners, and their consent had to be obtained both for these and for every other monument that has been since added to the list. This has entailed the examination and survey of all these monuments which are distributed over England, Scotland, and Wales. The addresses of the owners had to be obtained, and this could only be done on the spot. After that the owners had to be visited personally, for I soon found an official letter, without a verbal explanation, almost invariably produced a refusal. On this account I have of late found it advisable never to approach an owner without a personal introduction, or without doing it in such a way as to induce him to consider the matter favourably. This mode of procedure for the whole country has, of course, taken a long time, and the result has been that about half of these fifty monuments have been voluntarily put under the Act by their owners, and of the

¹ This refers to the work of the Prehistoric Remains Committee of the British Association.

remainder some of the proprietors have refused, whilst in the case of others it has been found impracticable owing to peculiarities in the ownership. All the monuments have, however, been carefully surveyed, planned, and drawn, and in every case in which there has been a refusal the owners have stated their intention of taking good care of the monuments themselves. In one case only a camp has been partly damaged, and this owing to mining operations involving a question of a large sum of money which made it impossible for the Government to interfere. Other non-scheduled monuments have since been added to the list, and the number is steadily but not rapidly increasing.

'The Government makes no allowance for an assistant, not even so much as a man to hold the end of the tape in measuring, without which no proper survey of the monuments can be made, and I have to employ a private assistant, whom I take about with me at my own cost. With his assistance, and by dividing the work with him—I making the necessary notes and measurements while he is drawing—each monument takes on an average about one day; without an assistant the time would be about doubled. After this the owner has to be visited, and as he generally lives at a distance from the monument, this frequently takes another day or more. A great deal of this time might be saved by the assistance of persons living in the localities, and with better chance of success.

'I issued a circular to a number of local Societies inviting them to co-operate, but few responded. One instance, however, shows what may be done in this way. Sir Herbert Maxwell has not only sent me the addresses of several owners in Wigtonshire and Kirkcudbrightshire, but, by using his influence with these, has been the means of placing several monuments under the Act. I would suggest that the same course might well be followed by others.

'The recommendation I would make is this:—Local Societies should (1) report to me what monuments in their district they think worthy of being 'put under the Act; (2) they should send me the names and addresses of the owners; (3) they should communicate with the owners, and, if possible, obtain their consent to have the monuments placed under the Act, subject, of course, to their subsequent acceptance by the Office of Works; and (4) they should report to me any damage that they find being done or contemplated either to the monuments under the Act, or to others not so protected. With such assistance I think that much more rapid progress may be made.'

Prehistoric Remains Committee.—Mr. J. W. Davis stated that this Committee had been recommended for reappointment by the Committee of Section H. The recommendation is as follows:—'That Sir John Lubbock, Dr. John Evans, Professor Boyd Dawkins, Dr. R. Munro, Mr. Pengelly, Dr. Hicks, Mr. J. W. Davis, Professor Meldola, and Dr. Muirhead be reappointed a Committee for the purpose of ascertaining and recording the localities in the British Islands in which evidences of the existence of prehistoric inhabitants of the country are found; and that Mr. J. W. Davis be the Secretary.'

Professor Lebour suggested that it would be convenient if, in registering prehistoric remains, the Committee would adopt a uniform scheme of signs—if possible an international one.

Mr. William Gray stated that the work of registering ancient remains had been carried on for 25 or 30 years by members of his Society (Belfast Naturalists' Field Club) and others in Ireland, and they had

long felt the want of some central organisation such as that of the present Committee. He also alluded to the necessity for a uniform system of signs.

Mr. William White remarked upon the difficulty which private individuals often experienced in approaching the proprietors of ancient remains, and pointed out that individual efforts would be likely to be more successful if members of local Societies could make overtures backed up by the sanction of a British Association Committee such as the present one.

STATUS OF THE CONFERENCE OF DELEGATES.

At the Manchester meeting of the Association an important resolution was framed at the instigation of Sir Douglas Galton with the object of conferring additional powers upon the Conference. According to the former rules the Delegates had no power of submitting resolutions or recommendations to the Committee of Recommendations, but the resolution referred to is calculated to give them the necessary power, and thus to put the Conference on the same footing as the Sectional Committees. The resolution in question was passed last year, on the motion of the Secretary of the Corresponding Societies Committee, by the Committees of Sections B and C, and had been accepted in due form by the Committee of Recommendations and by the General Committee, so that it is now a rule of the Association. The resolution is as follows:—

‘That the Conference of Delegates of Corresponding Societies be empowered to send recommendations to the Committee of Recommendations for their consideration, and for report to the General Committee.’

Nomination of Delegates.—At the Conference of Delegates held last year the Secretary of the Corresponding Societies Committee stated that some of the local Societies had nominated delegates to attend the Manchester meeting without having previously submitted any claim for admission as Corresponding Societies. This probably arose from a misunderstanding of the rules, and the Corresponding Societies Committee has to point out that such Delegates cannot be officially recognised by the Association, as it is only those Societies which have been admitted as Corresponding Societies, and which are still on the list, that are thus entitled to be officially represented. *According to the Rules no Society can be admitted without first sending in a formal application, accompanied by a specimen of its publications; this application would be considered by the Corresponding Societies Committee, and only in the event of the Society being recommended for election by this Committee, and this recommendation being confirmed by the General Committee, would it be admitted to the privileges of a Corresponding Society.*

The Corresponding Societies Committee recommends that all the Societies on last year's list should be retained, and that the Belfast Natural History and Philosophical Society, the Leeds Geological Association, and the Nottingham Naturalists' Society should be enrolled as Corresponding Societies.

The Corresponding Societies of the British Association for 1888-89.

Second Report of the Committee, consisting of Sir JOHN LUBBOCK, Dr. JOHN EVANS, Professor BOYD DAWKINS, Dr. ROBERT MUNRO, Mr. PENGELLY, Dr. HENRY HICKS, Professor MELDOLA, Dr. MUIRHEAD, and Mr. JAMES W. DAVIS, appointed for the purpose of ascertaining and recording the localities in the British Islands in which evidences of the existence of Prehistoric Inhabitants of the country are found. (Drawn up by JAMES W. DAVIS.)

IN the report presented last year it was proposed that distinctive signs should be adopted to indicate the character of prehistoric objects on maps. This subject has had careful attention and it is recommended:—

I. That the one-inch ordnance survey map may be used.

II. That the signs and colours adopted by the Commission appointed by the International Congress of Anthropologists and Archæologists at Stockholm in 1874 be employed. The Commission consisted of representatives of eleven European countries; the one for Great Britain was Dr. John Evans. The subject received long and serious discussion, and the results have been generally accepted; they are tabulated at considerable length in the 'Comptes Rendus du Congrès,' vol. ii. p. 937 *et seq.* 1876. For the purposes of this committee the signs given below will probably suffice; should more specialised signs be required the recorder may be referred to the 'Comptes Rendus.'

1. Caves and caverns	
2. Camps and earthworks	
3. Lake-dwellings and crannoges	
4. Menhirs	
Dolmens	
5. Barrows or tumuli	
Other burial-places	
To which may be added:—		
6. Kjökkenmödding	

The different ages of the objects may be indicated by colour if the objects are extended over considerable areas; or, by signs if the objects are single, or too limited in area to be represented by colour.

Thus:—

	Colour.	Signs.
1. Palæolithic stone age . . .	Yellow-brown	↑
2. Neolithic stone age . . .	Green	↑
3. Bronze age . . .	Red	✕
4. Iron age . . .	Blue	□

It may be noted that the more rudimentary state of civilisation is represented by the simplest sign, and as the civilisation becomes developed the sign becomes more complex.

A combination of the signs indicating age may be made with those given previously which show the character of the object.

During the past year a list of prehistoric objects found in Derbyshire has been compiled and is appended herewith. Others are in course of preparation and will be available for future reports. In addition to the names of gentlemen who have undertaken to record the occurrence of objects in the localities also indicated which were printed in the report of last year, the following have signified their intention to furnish material for the purposes of the Committee, viz.:—

M. G. Stuart, Esq., Hon. Secretary of the Dorset Natural History and Antiquarian Field Club, for the county of Dorset.

Henry Wilson, Esq., Malvern Link, for the counties of Worcester and Herefordshire.

William Gray, Esq., of Belfast, for the counties of Antrim and Down.

George H. Parke, Esq., of Furness Abbey, for North Lancashire and Westmoreland.

On the Prehistoric Inhabitants of Great Britain.

DERBYSHIRE.

Recorder.—Rev. J. MAGENS MELLO, M.A., F.G.S., local secretary for Derbyshire, Soc. Antiq., Lond.

Burnt bones .	" "	"	"	" "	—	—

N.B.—Although the Church Hole Cave is, strictly speaking, in Nottinghamshire, it will probably be considered most convenient not to separate its contents from those of the other caves belonging to the same group.

In cataloguing the Prehistoric remains found in the Derbyshire Tumuli I have found it almost impossible to separate the Neolithic from the Bronze age interments, owing to the constant intermingling of the two, and therefore I have grouped them together under one heading. The two civilisations naturally blend; there is no such gap between them as there is between the Palæolithic and Neolithic ages.

TABLE II.—*Neolithic and Bronze Ages.*

Name of Object	Locality	Previous Description	Remarks
1. EARTH-WORKS AND FORTIFICATIONS.			
1. Pit dwellings.	Crich, Linda Spring Wood	'Vestiges of the Antiquities of Derbyshire.' By T. Bateman and S. Glover. ('V. A. D.' used to denote this work.)	2 rows of circular pits, called the Pitsteads, each about 15 ft. diam., 6 ft. deep.
2. " "	Abney Moor . . .	'Barrows and Bone Caves of Derbyshire.' R. Pennington.	Excavated in the rock.
3. Quadrangular enclosures	Smyrrill Grange, near Middleton-by-Youlgrave	'V. A. D.' . . .	4 yds. to 10 yds. square, built of Limestone blocks. Coarse pottery within.
4. Stone pavements	Harthill Moor . . .	" . . .	Supposed floors of circular huts.
5. Camp . . .	Mam Tor, Castle-ton	" also 'Barrows and Bone Caves,' &c.	—
6. Fort ? . . .	Alport Castle. . .	" "	Barrows and fort ? Remains of rampart of rough stones.
7. Fort or camp.	Markland Grips, near Creswell	—	—
8. Fort ? . . .	Carlsward, Hathersage	'V. A. D.' p. 122; 'Ten Years' Diggings,' p. 253; 'Reliquary,' vol. i. 159; 'Archæologia,' vol. vii.	Encampment walled with large stones.
2. CIRCLES.			
1. Megalithic circle	Arborlow . . .	'V. A. D.' . . .	Circle of Limestone blocks overthrown, surrounded by a ditch and vallum; connected by a serpentine vallum with a tumulus $\frac{1}{2}$ mile distant. Barrows near circle.
2. Circle . . .	Harthill Moor, ('Ninestone Close')	" . . .	7 rude stones; 2 others 80 yds. to S.
3. " . . .	Brassington Moor . . .	" . . .	Circle of 2-ft.-high stones, 39 ft. diam.; another smaller (22 ft. diam.) 16 ft. distant.
4. " . . .	Abney Moor, near Highlow Moor	" . . .	33 ft. diam., enclosed by vallum; 4 large upright stones within. In 1755 there were 9 large equidistant stones.
5. " . . .	Eyam Moor, Wet Withens	" . . .	16 upright blocks of gritstone, 30 yds. diam.; there was a large central block.
6-18. Circle . . .	" "	" . . .	At least 12 more circles, each surrounded with circular mounds of earth, some with stones.
19. " . . .	Froggatt Edge . . .	" . . .	About 12 yds. diam., with central block.
20. " . . .	East Moor, Baslow	" . . .	13 stones; 12 yds. diam.
21. " . . .	Hathersage Moor . . .	" . . .	6 stones; one 7 ft. high near.
22. " . . .	Stanton Moor ('Nine Ladies')	Figured, 'V. A. D.' p. 112	9 erect stones, 3 ft. to 4 ft. high; 1 stone 34 yds. distant.
23. " . . .	Offerton Moor . . .	'Barrows and Bone Caves of Derbyshire.' R. Pennington.	89 ft. by 83 ft.; rampart 7 ft. wide.
24. " . . .	Wet Withens Moor	" "	100 ft. diam.; rampart 17 ft. wide; 11 stones standing.
3. ROCKING STONES.			
Rocking stones . . .	Stanton Moor, Birchover (Row-to Rocks)	'V. A. D.' p. 115, &c. . .	An outlier of Kinderscout Grit had several rocking stones.
" " . . .	Bradley Tor, near the above	" . . .	$\frac{1}{2}$ mile from the above another outlier with rocking stone.
" " . . .	Ashover Common ('Robin Hood's Mark')	" . . .	—
" " . . .	Hathersage Moor . . .	" also Spencer Hall's 'Rambles in the Country,' p. 28.	Several stones in this locality; were movable in 1842.

TABLE VII.—NEOLITHIC AND BRONZE AGES—*continued.*

Name of Object	Locality	Date	Previous Description	Where Deposited	Length	Remarks
Contracted sitting skeleton; chipped flints; broken urn	Parcelly Hay (Hartington)	1848	'Ten Years Diggings,' by T. Bateman. 'T. Y. D.' used to denote this work. A Descriptive Catalogue of the Antiquities, &c. preserved in the Museum of Thos. Bateman	Bateman Collection, Weston Park Museum, Sheffield	Ins. —	Cist and skeleton figured 'T. Y. D.,' p. 23
Skeleton contracted; granite axe head; bronze dagger	—	—	" "	" "	—	This interment was on the covering stones of the above, axe head perforated; dagger with 3 studs
Fragments of skeletons and burnt bones; whet-stone; flint arrow head; female skeleton contracted; skeleton of child	Middleton Moor, near Arborlow	1848	" "	" "	—	Leaf shaped arrow head; cow's tooth found with skeleton, an article Bateman says uniformly found with the more ancient interments
Necklace of jet and bone beads	—	—	" "	" "	—	Consisted of 420 beads found round neck of the woman's skeleton, see 'T. Y. D.,' figured, p. 25
Calcined bones; broken urn	Sharp Low, near Tissington	1848	" "	" "	—	—
Contracted skeleton; broken urn	Near Thorpe Cloud, Dove-dale	1848	" "	" "	—	—
Skeleton; bronze celt; bronze dagger; jet bead; circular flint implement	Parwich Moor	1848	" "	" "	—	This skeleton had been wrapped in a dark red skin, traces of the hair left around it and on the bronze weapons, on which are also traces of fern leaves by which the body was surrounded. 'T. Y. D.,' p. 34
Burnt bones; coarse urn; flints	Round Low (Hopton)	1848	" "	" "	—	—
Skeleton; burnt bones; flints; small coarse urn; 2 skeletons; small urn	Crake Low (Tissington)	1848	" "	" "	—	—
	—	1848	" "	" "	5.5 hgh	—

TABLE VII.—NEOLITHIC AND BRONZE AGES—*continued.*

Name of Object	Locality	Date	Previous Description	Where Deposited	Length	Remarks
Skeleton; bronze dagger; flint spear head	End Low, near (Hartington)	1848	Ten Years' Diggings, by T. Bateman	Bateman Collection, Weston Park Museum, Sheffield	Ins. 6½	Skull engraved in Crania Brit., dagger figured 'T.Y. D.,' p. 39
Fragments of flint; fragments of skeletons; 2 skeletons; contracted flint spear head; flint chips	Moneystones (Hartington)	1848	'A Descriptive Catalogue of the Antiquities, &c., preserved in the Museum of Thomas Eateman'	" "	—	—
6 skeletons; 4 flint implements; fragments of urn; contracted skeleton of girl; bones of an infant; small vase; fragments of small vase	Blake Low, Longstone Edge	1848	" " "	" "	—	—
Burnt bones of man; skeleton of child; 2 urns; fragment of flint	Blake Low, Longstone Edge	1848	" " "	" "	7.5 high	—
Contracted skeleton; flint spear head; flint arrow head; contracted female skeleton; skeleton of infant	Middleton-by-Youlgrave	1848	" " "	" "	—	—
Broken clay cup					—	The cups highly ornamented
Flint implement; fragments of cup; flint arrow head; part of a quern					—	—
Fragments of skeleton; fragments of calcined flint implements; bone spear head	Youlgrave (Greenstor Meadow)	1848	" " "	" "	—	—
Contracted skeleton; flint arrow head; fragment of stone celt	Borthor Low, Middleton	1849	" " "	" "	—	—
3 contracted skeletons; some flint implements	Grind Low, Over Haddon	1849	" " "	" "	—	—
73 jet beads (necklace)						Necklace figured 'T.Y. D.,' p. 48
Broken flint spear head						—
Skeleton of infant; fragments of urn	Parwich	1849	" " "	" "	—	—
Contracted skeleton; 2 skeletons; flint implement	Vincent Knoll, (Parcelly Hay)	1849	" " "	" "	—	—
Contracted skeleton; leaf-shaped flint dagger; flint spear head; skeleton; flint flake; fragment of hæmatite; jet head; 2 skeletons; flint arrow head; flint implement	Chelmorton, Netherlow	"	" " "	" "	4.5	Lower half of dagger serrated
Contracted skeleton; circular flint implement; burnt human bones	Cronkstone Low (Hartington)	1849	" " "	" "	—	—
Burnt human bones; flint implements; broken bone implement	Minning Low (Brassington)	"	" " "	" "	—	A stone cairn barrow with a later earth mound attached

TABLE VII.—NEOLITHIC AND BRONZE AGES—*continued.*

Name of Object	Locality	Date	Previous Description	Where Deposited	Length	Remarks
Bronze dagger . . .	—	—	'Ten Years' Digging's,' by T. Bateman. 'A Descriptive Catalogue of the Antiquities, &c., preserved in the Museum of Thos. Bateman'	Bateman Collection, Weston Park Museum, Sheffield	Ins.	Dagger archaic in form, holes in it for thongs, no rivets, dagger contorted by fire
Burnt bones; fragments of urn; 4 skeletons	Ballidon Moor	"	" " "	" "	—	Ballidon Moor barrow figured 'T. Y. D.,' p. 60
Contracted skeleton . Burnt and unburnt human bones	—	"	" " "	" "	—	Skull of contracted skeleton is engraved 'Crania Britannica,' typical Brachycephalic
Fine urn with burnt bones	—	"	" " "	" "	—	Urn figured 'T. Y. D.,' p. 59
Flint arrow head	—	"	" " "	" "	—	—
Skeleton of child; fragment of ornamented pottery	Ryestone Grange (Minning Low)	"	" " "	" "	—	—
Burnt bones; flint chips; fragment of stone celt	Flax Dale Barrow (Middleton-by-Youlgrave)	"	" " "	" "	—	Barrow figured 'T. Y. D.,' p. 63
Burnt bones; small vase; fragments	Calton Pasture (Chatsworth)	1850	" " "	" "	—	—
Extended skeleton; flint implement	Hasling Houses (Buxton)	"	" " "	" "	—	Skeleton perhaps Saxon. —T. B.
81 jet beads and plates; several disturbed skeletons	Hill Head (Buxton)	"	" " "	" "	—	—
Bronze awl; skeleton; flint implement	Stakor Hill (Buxton)	"	" " "	" "	—	—
2 contracted skeletons; large flint implement; 2 small flint implements	Vincent Knoll	"	" " "	" "	—	—
Burnt bones; flint chips	Upper Edge (Sterndale)	"	" " "	" "	—	—
Fragments of 4 skeletons; burnt bones; fragments of vase; bone implement	Crakendale Pasture (Bakewell)	1851	" " "	" "	—	—
Contracted skeleton; 3 bronze implements; contracted skeleton	Bee Low (Youlgrave)	"	" " "	" "	—	—
Drinking cup . . .			" " "	" "	8.75 high	Cup ornamented by two variations of lozenge pattern
Flint implement . . .	—	"	" " "	" "	4	—
Burnt bones; bronze pin; skeleton; 2 flint implements; fragment of infant's skull	—	"	" " "	" "	—	—
Fragments of skeletons; broken urn; skeleton; skeleton of child; 2 flints	Monsal Dale .	"	" " "	" "	—	—

TABLE IX.—Neolithic and Bronze Ages.

NOTE ON THE BURIALS RECORDED BY T. BATEMAN.
(Compiled from 'The Barrows and Bone Caves of Derbyshire.')

Corpse Extended	Corpse Contracted	Corpse Burnt	Total
I. BARROWS CONTAINING STONE IMPLEMENTS ONLY.			
1	76	40	117
II. BARROWS CONTAINING STONE AND BRONZE IMPLEMENTS.			
1	18	12	31

NOTE.—The late Mr. Rooke Pennington, from whose work the above data are derived, has shown that infanticide was probably not uncommon during the Neolithic and Bronze Ages, no fewer than twenty-three cases of children's bones buried with adults having been found in the Barrows, the ages of the children being between four years and ten years. The adults were very frequently females. Of the twenty-three cases only four occurred in Barrows containing bronze alone, and one in a Barrow where the two classes of implements were mixed.

The general practice amongst the Neolithic populations and those of the Bronze Age seems to have been to bury the bodies in a contracted position, the knees being drawn up towards the chin. Cremation was also very generally prevalent during the whole period.

Third Report of the Committee, consisting of Sir JOSEPH D. HOOKER, Sir JOHN LUBBOCK, Sir GEORGE NARES, General J. T. WALKER, Sir LEOPOLD MCCLINTOCK, Admiral Sir GEORGE H. RICHARDS, Professor FLOWER, Professor HUXLEY, Dr. SCLATER, Professor MOSELEY, Mr. JOHN MURRAY, General STRACHEY, Sir WILLIAM THOMSON, and Admiral Sir ERASMUS OMMANNEY (Secretary), appointed for the purpose of drawing attention to the desirability of prosecuting further research in the Antarctic Regions.

SINCE the meeting held at Manchester last year the above Committee have been in communication with the scientific bodies in Australia, New Zealand, and Tasmania. These colonies have manifested a very great desire for exploration of the Antarctic regions, which is strongly advocated by their respective Governments. The result is that the Government of Victoria voted the sum of 5,000*l.* towards an expedition, provided that the Imperial Government contributed a similar grant.

The Colonial Office submitted the application to H.M. Treasury for favourable consideration, who sent it to the Royal Society for their report on the expediency of the undertaking. A very influential committee was accordingly appointed by that learned body to consider the matter. The reply from the Royal Society together with a letter from the Colonial Office and the Treasury are annexed herewith, which sufficiently explains the motives for declining to make the grant.

It may be inferred from the tone expressed in the official letters that H.M. Government is favourably disposed towards the despatch of an expedition efficiently equipped for the perils of Antarctic research. It is therefore to be hoped that the leading scientific societies and men of eminence in this country may combine in preparing a case to submit to H.M. Government that will justify an appeal to Parliament for an expedition being prepared on a scale equivalent to the one which met with such valuable results under Sir James Ross.

It should be stated that the subject has been brought under the notice of the Admiralty, and your Committee have met with the support of the Royal Geographical Society and other influential bodies, besides eliciting favourable encouragement from men of great eminence in the promotion of science.

Your Committee, having thus given publicity to this desirable project, feel that their services are no longer required at present, but they trust the Council of the British Association may embrace an early opportunity for approaching H.M. Government to carry out this noble work of research into the Antarctic regions.

Downing Street, December 12, 1887.

I am directed by the Secretary of State for the Colonies to transmit to you, to be laid before the Lords Commissioners of the Treasury, a copy of a letter from the Agent-General for Victoria, inquiring whether Her Majesty's Government will contribute the sum of 5,000*l.*, in the event of the Australian Colonies making a like contribution, towards the cost of an Antarctic exploration. Copies of letters on the subject are also enclosed from the Admiralty, the Royal Colonial Institute, the Royal Geographical Society, and the Royal Society, which their Lordships will observe are all in favour of the co-operation of Her Majesty's Government in this work. A reference was also made to the Board of Trade, and it will be seen from the accompanying copy of their reply that in their opinion it does not appear necessary in the interests of trade that Her Majesty's Government should contribute towards the expense. The Board of Trade do not, however, seem to have regarded the probability of a considerable trade in sperm oil and other products of whale fishery arising in the future, or the importance of the expedition for scientific purposes, which it is believed would constitute the principal object of the expedition, and the value of which is strongly attested by the Royal Geographical Society and the Royal Society. Sir H. Holland trusts their Lordships will give their favourable consideration to this application on behalf of the Government of Victoria and consent to the contribution of the sum of 5,000*l.* towards the scientific objects of the expedition. It would seem undesirable for Her Majesty's Government to take any direct share in the equipment or management of the expedition.

I am, &c.,

JOHN BRAMSTON.

The Secretary to the Treasury.

Treasury Chambers, January 3, 1888.

The Lords Commissioners of Her Majesty's Treasury request you to inform Secretary Sir Henry Holland that they have had before them Mr. Bramston's letter of the 12th ultimo, submitting for their favourable consideration an inquiry, made by the Agent-General for Victoria, whether Her Majesty's Government would contribute 5,000*l.* towards the cost of an expedition to explore the Antarctic regions, if such an expedition were undertaken by the Australian Colonies. The objects of this expedition would be (1) the promotion of trade and (2) scientific inquiry. But the department best able to judge of the first does not think the interests involved sufficient to justify the proposed imperial contribution; and the general result of the communications regarding the second object, received from scientific bodies, is to show that an expedition on the scale contemplated could do very little in the way of scientific investigation, and would have to be regarded simply as a pioneer of future more complete and costly expeditions. In view of this testimony, and of the many other pressing calls for imperial aid which they have felt it necessary to refuse, my Lords do not feel that they would be warranted in asking Parliament

to provide the proposed contribution. They arrive at this conclusion, however, with sincere regret, and would have been glad to have co-operated with the Australian Colonies in an enterprise having something more than a merely commercial purpose. Perhaps, however, my Lords may be allowed to regard the present proposal as an indication that if any like expedition be undertaken hereafter by the Imperial Government some of the British Colonies more closely interested in it might not be unwilling to contribute towards its cost.

C. G. BARRINGTON.

The Under-Secretary of State, Colonial Office.

The Committee appointed (October 27) to consider and report upon the letter from the Colonial Office having reference to the question of an Antarctic expedition beg leave to embody their report in the following draft reply :—

Sir,—Your letter of August 27, with enclosures relative to a proposed Antarctic expedition, has been carefully considered by the President and Council, with the assistance of a committee consisting of Fellows of the Society specially qualified to form a judgment on the matter, and I am directed to reply as follows :—

Many observations of great scientific value might be made in the Antarctic regions, and it would be very desirable in the interests of science to embrace an opportunity of making them. Among such observations may be mentioned, in what is perhaps the order of their importance—

1. Hydrographical observations, especially with regard to the distribution of open sea.

2. Meteorological observations, especially with regard to the barometric pressure and the direction of the winds, to which may be added observations on the Aurora australis.

3. Magnetic observations, more particularly with a view to determine the changes which have taken place in the magnetic elements since the expedition of Sir J. Ross in 1839–43.

4. Observations on the temperature of the ocean and on ocean currents.

5. Soundings and dredgings and observations on the nature of the sea-bottom.

6. Collections and observations on the marine fauna and flora.

7. Should land be anywhere discovered geological and biological observations thereon would be of exceedingly great value.

It is obvious that an expedition adequately prepared and equipped to carry out all the above various observations would involve an expenditure far exceeding the 10,000*l.* mentioned in your letter; but the President and Council are led to believe that this sum would suffice for a smaller pioneer expedition, which, while avowedly not designed to undertake an exhaustive inquiry, would be able, under competent direction, to make a careful survey of the northern boundary of the circumpolar ice region to determine approximately the distribution of open water and the direction of oceanic currents, to take magnetical and meteorological observations, and, by means of the tow-net and the dredge, used at moderate depths, to collect pelagic animals and plants.

The results of such a general survey, even though not wholly complete, would not only of themselves be of great interest and value, but

also be of paramount importance in guiding a decision as to the desirability, or the contrary, of sending out in the future expeditions more thoroughly equipped for special observations, and in preparing the way for such expeditions, should the preliminary results seem to render these desirable.

Should H.M. Government, therefore, decide to accept the proposal of the Government of Victoria, and to place the sum in question on the estimates of the coming year, the President and Council will regard that decision with great satisfaction, and I am directed to say that such further assistance or advice as they can give is at the service of H.M. Government.

In their deliberations on the matter the President and Council were much assisted by a memorandum drawn up by Admiral Sir G. H. Richards and another by Sir J. D. Hooker. These memoranda, written by gentlemen having very special qualifications derived from exceptional experience for offering important suggestions, contain so much that is interesting and valuable that copies of them have been enclosed with this letter. Should you think it desirable that the Colonial Governments should be acquainted with these memoranda copies of them will be placed at your disposal.

I have the honour to be, &c.,
(Signed) M. FOSTER.

Report of the Committee, consisting of Dr. ALEX. BUCHAN, Professor MCKENDRICK, Professor CHRYSTAL, and Dr. JOHN MURRAY (Secretary), appointed for the purpose of aiding in the maintenance of the establishment of a Marine Biological Station at Granton, Scotland.

DURING the past year the Committee have maintained, for the use of naturalists desirous of making use of them—

1. A laboratory at Granton, near Edinburgh;
2. A small laboratory at Millport, Cumbrae, in the Firth of Clyde;
and
3. The steam yacht 'Medusa,' which has been employed throughout the year carrying on continuous physical and biological observations.

A large number of naturalists have availed themselves of these facilities, and many important investigations have been carried on and the results published. Papers on some of these will be submitted to this meeting of the Association by Dr. Mill, Mr. Hoyle, and others. A large number of specimens of the British fauna have been sent to the British and other Museums.

The Committee believe that these investigations are of much value, and should be continued and the laboratories maintained as heretofore; and with this object they beg to recommend that a further grant of 100% should be made by the Association to aid in the maintenance of the Scottish Marine Station during the ensuing year.

Report of the Committee, consisting of Mr. H. BAUERMAN, Mr. F. W. RUDLER, Mr. J. J. H. TEALL, and Dr. H. J. JOHNSTON-LAVIS, appointed for the investigation of the Volcanic Phenomena of Vesuvius and its neighbourhood. (Drawn up by Dr. H. J. JOHNSTON-LAVIS, F.G.S., Secretary.)

THE reporter is glad to be able to announce that since last year some very interesting additions to our knowledge of this region have been made, some of which have a very important bearing on general questions in vulcanology.

Geological Map of Vesuvius and Monte Somma.—It is with a feeling of relief that the reporter is able to lay before the British Association his work in a completed state. The preparation of the last sheet gave equal trouble with the other three of the south side of the mountain, the district being covered with habitations and high garden walls. The mapping of the dykes of the Atrio del Cavallo, which had been left from the other sheets, was carried out during the month of June of this year, and required residence near the Observatory. As far as space and a plan map of a very steep section would allow, all the principal dykes have been marked in. The reporter has numbered forty of the more striking of them in large figures, from one to four feet high, in white paint, which correspond to similar numbers on the geological map. Specimens of the salband and interior of all these have been collected, and will be subjected to suitable investigations; also notes regarding the characters as observed in the field, together with thickness, &c., have been made. An examination of this section has revealed at least half a dozen hollow dykes, similar to that giving rise to the eruption of May 2, 1885, which the writer was able to study the formation of and describe, and has since observed at Stromboli and Vulcano. Amongst those of Monte Somma, one was observed full at the lower part of the section, but hollow at the upper, showing that it had just drained out to the level of the parasitic cone or lateral eruptive mouth that had been formed.

Most important, however, was a dyke near the western end of the Atrio section, which can be seen to be a hollow dyke refilled, and the second filling to have been in part drained out, leaving a lava tunnel.

The object of numbering the dykes in white paint is to identify them both on the map and in the field, and to serve as a guide to anyone who may care to investigate them. Many years since R. Mallet numbered twenty-seven of them in red (not sufficiently conspicuous), but no signs of such could be met with. It would be well worth the trouble to have these numbers repainted every two years, which could be done by any ship's painter for a few francs.

State of Vesuvius.—During August 1887 the crater of 1885 had not further increased. It, as mentioned in the last report, was divided into two crateral depressions, the active being the easterly one. To its north side there is still visible a remnant of the old 1881–2 rim, whilst its southern was split by a deep gully, the remains of the old fissure above the dyke that gave origin to the lava outpour of May 2, 1885. An attempt was being made to build up a cone of eruption. During the whole time since then this cone of eruption has been growing, and has now

reached nearly to the level of the crater edge (June 10, 1888). The activity of the volcano has been most constant, generally ranging from first to second degree, and never exceeding the third. Lava, as in my last report, has continued to flow without cessation, varying slightly in quantity. It has been chiefly occupied in oozing forth in different parts of the Val d'Inferno, which it has further choked by piling up hills of no considerable volume.

An examination of the materials withdrawn from Russo's well at Ponticelli, mentioned in last year's report, is not yet complete. It will be remembered that after descending nearly 50m. below sea-level, leucitic lavas were met with, with a thickness of over 50m. Beneath these lavas, from 105.44m. to 107.50m., beautiful rounded pebbles and sand are met with. These consist of rounded fragments of a trachyte which strikingly resembles that of the larger mass met with in the tunnel of the Cumana railway at Naples. More important, however, were beautiful black pebbles of a typical basalt, indicating that either from Vesuvius or the neighbouring volcanic region this rock had been poured out at an early date in the history of the eruptive activity of this region.

This discovery is of still further importance in regard to theorising on the sequence of rocks erupted in a given region, which will be further on referred to.

EXCAVATIONS NEAR NAPLES.

Cumana Railway.—Geologists, engineers, and contractors, all believed that the hills which back Naples, and are prolonged into the promontory of Posilippo, consisted of a fairly uniform mass of yellow tuff. In last year's report mention was made of large masses of trachyte being found in the new railway tunnel, which is now near completion, and exhibits from beginning to end sections of deep interest, both local and general. Investigations are being carried on continually from the stratigraphical, lithological, petrographical, and chemical aspects of the subject, but are not yet complete, and therefore will only be referred to in general. Entering the tunnel from Monte Santo, we meet with 530m. of tuffs, which are capable of various subdivisions. From this point to 910m. one continuous mass of trachyte is met with, that is for near upon half a kilometre. This trachyte is in some places compact and very fine grained, in others soft and spongy. At some spots thick beds of sodalitic fine-grained scoria covering the surface may be seen, and in other places beds of blacker scoria, as if near an eruptive cone, occupy a similar position. The scoriaceous surface continuous with the underlying compact trachyte mass could be well seen at 730m. Unfortunately much is soon covered up by masonry, so that frequent visits must be made to keep one thoroughly *au courant* of the discoveries.

This mass of trachyte is followed by yellow tuffs with variable coarseness, compactness, and other characters, which graduate into a greenish grey mottled with yellow tuff, and this eventually into a pure greenish grey tuff. We have most distinct evidence of the gradual formation of a yellow tuff from a compacted mass of fragments of pumice and scoria. The process is distinctly due to the hydration of the glassy part of the pumice and scoria. In many examples the surface of a block of pumice has undergone this change, leaving an unaltered nucleus. The chemical and microscopical changes involved in this process are undergoing investigation, and will soon be published in full.

Later on yellow tuffs appear again, until at 1,890m. the great mass of trachyte, referred to last year, continues for 110m. This will probably be looked upon in future as the most beautiful specimen of sodalite trachyte known, whilst its cavities, where the rock is vesicular, are lined by some six or seven species of minerals. At both ends it is seen to be limited by an escarpment, against which a talus of its own blocks exists, and over these, but similarly inclined, a number of pumice and ash beds, followed by compact tuffs. The remaining part of the tunnel is cut in the compact yellow tuff of the district, except near its mouth, where it is overlaid by the usual loose pozzolana. The same railway traverses the Posilippo ridge parallel to the two existing tunnels, but, like them, traverses compact yellow tuff.

On the road to Pozzuoli, just beyond the thermo-mineral baths of La Pietra, of Bagnoli, a yellow tuff has been cut down, upon which exists a raised beach composed of large, more or less rounded, masses of the same. In the interpaces between these, as the result of solfataric action, beautiful branched efflorescent masses of gypsum were met with, attached to the surface of the tufa.

Not far beyond this, a tunnel is in course of construction which runs parallel to the cliff and road, and only a few mètres from the surface. The beginning, or Naples end of it, is cut in sand, breccia and gravel constituting the raised beach underlying the trachyte eruptions of the solfatara, and eventually enters the deposits of black scoria belonging to the same. The heat is so intense that work was suspended till the ventilating windows and shafts, now being made, be finished.

The last point of importance on this line, is the tunnel intended to be cut through the hill of Baja, of which in the last report doubts were expressed as to the practicability. This work has only been commenced a few days, at the entrance beneath the baths of Nero, but the altered pumice in the tuff, deposits of silica in fissures, and a gradually increasing temperature seem pretty sure indications of the difficulties to be contended with.

Collettore Pluviale delle Colline.—The main collector of the pluvial water from the hills backing the west of Naples is now nearly complete. It may be said to run roughly parallel with the Cumana Railway tunnel, but at some distance from it and at a lower level. In this a mass of trachyte was traversed for 28m. It differs from both the masses of the Cumana Railway tunnel in some of its characters, but approaches mostly the smaller one to which it is more nearly situated. What is very interesting about it is that its fissures (it is not vesicular) are often lined by beautiful octahedra and pseudoprisms of what was once sodalite, but is now nothing more than a shell, of bright brick-red colour, of a mixture of substances which has replaced the original mineral. In some places the latter is unaltered, and all gradations can be met with in the process. This mineral and its products are accompanied by many needles of titanite, amphibole, some zeolite, &c. This trachyte is enveloped in the Rione Amedeo tuff, but going west this is overlaid by the usual compact yellow tuff, and eventually pozzolana. In the tuff near the trachyte blocks of piperno were met with, and in the Rione Amedeo large masses of grey plastic clay (Pliocene), quite unaltered and containing many fossils.

Funicular Railway of Rione Amedeo.—This work, composed principally of a tunnel with some open cutting, is placed above and at right angles to the Cumana Railway and the Pluvial Collector, and joins a side adit

from the former. We have at its lower part Rione Amedeo tuff, superimposed upon which come beds of pumice and ash, continuous with the well-known synclinal fold of these beds on the Corso Vitt. Emmanuele. Above this comes the common yellow tuff.

Funicular Railway of Monte Santo.—This is only in the early stages of construction, but is likely to afford very important data for disentangling the complex structure of the Campi Phlegreæ. Entering the tunnel from the Corso Vitt. Emmanuele, some four mètres (vertical measurement) of a loose brown pozzolana are met with, in which occur fine-structured, dirty-white pumice. This is overlaid by a bed of small white pumice lapillæ without any *accessory* or accidental ejectamenta superimposed, upon which comes 4m. of similar pumice, interstratified with thin bands of pozzolana of buff or red colour. Upon these deposits we have another greyish-white pumice bed 0·80m. thick, and composed of large masses, up to the size of a cocoa-nut. The upper part of this pumice has undergone a peculiar reddening, which I shall refer to later. Above this is a black ash-band 0·10m. thick, and then about 4·50m. of grey pipernoid tuff, the lowest 0·30m. of which is red in colour, and shades into the grey above. This tuff is identical in character with similar tuffs of Sorrento, Nocera, Capua, and Roccamonfina, and contained a small block of piperno with large marialite crystals. Superimposed on this comes 2·50m. of coarse breccia of reddish pumice with numerous large blocks, consisting of pieces of vitreous piperno, sodalite trachyte, a bright red vesicular basic rock (andesite?), pyroxenic lava (dolerite?), tuffs of various kinds, and pieces of black obsidian. At the opposite or descending end of the tunnel only yellow tuff has, so far, been met with.

To appreciate the value of these sections, it is necessary to refer to some others in the neighbourhood. The breccia bed in this section is identical with that overlying the piperno of Pianura and Soccavo. The banded ash and pumice beds are identical with some seen underlying the above-mentioned breccia behind Soccavo, and the grey pipernoid tuff is stratigraphically in the same position as the piperno of those localities; besides, it contained a most characteristic fragment of that rock, made doubly certain by the marialite crystals. The facts, I think, are sufficient to satisfy anyone that piperno and this grey pipernoid tuff are derived from the same source. But beyond this, at Fossa Lupara, between Nocera and Sarno, this same grey tuff is red at the bottom and reposes on a reddened pumice, like that in the section of Monte Santo Funicular Railway tunnel; whereas, at the Codola tunnel, near Nocera, a thin bed of white pumice underlies the grey tuff.

In both these cases the pumice is smaller, and in the latter small in quantity, as if transported aerially from a great distance. These conclusions immediately bring up in our thoughts the unsettled question as to what is the piperno of Pianura and Soccavo. There it has all the compactness of a lava, with distinct evidence of flow structure in its components. Elsewhere it looks like a tuff. It is supposed by some to be a metamorphosed or refused tuff in places; but if that were so the underlying pumices at Soccavo should have been similarly altered. Besides, at Soccavo, at the west end of the section, two distinct beds of piperno may be met with (I believe so far unnoticed by other observers), interstratified with similar materials as far as heat could influence them, whilst the pipernoid banding of the ejected blocks immediately overlying

them is oriented in all directions, a fact sufficient to negative all question about refusion or metamorphism, unless this took place on the surface of the ground. Lastly, pieces of peculiar yellow tuff enclosed in the massive piperno, in the overlying breccia blocks at Pianura, at Soccavo, and also at Naples, are quite unaffected by fusion, or changed more than what would occur by being caught up in a quickly cooling lava stream. Two explanations remain open to my mind. First, piperno is a true lava, of which the grey tuffs are the cinders and ashes of the more explosive stage of the eruption or eruptions. Against this we have the stratified structure of piperno, independent of its banding due to the presence of more or less in number of the enclosed blacker lenticles, and secondly, the long, thin bed of uniform thickness of the upper piperno of Soccavo. Secondly, the eruption of magma towards the end of at the beginning of an eruption, fairly free from aqueous inclusion, which, falling still hot, became more or less fused together in the immediate neighbourhood of the vent, as may be seen at any active volcano. In favour of this we have the fact that often the piperno appears to be composed of fragments in part fused together, as if the heat were insufficient to complete the operation. In both cases we must suppose a mixture of two magmas. They may, however, be nothing more than the same one, part from the upper, cooler portion of the chimney and part from the lower, hotter and more aquiferous, just as in the banded trachytes of Palmarola. This is supported by the ejected blocks having the black part composed of obsidian, whilst the grey is much more vitreous than the massive rock.

To limit this report, the remaining conclusions are given categorically, open to correction in the studies to be published in full:—

The oldest rocks, so far known in mass near Naples, are the sodalite trachytes of the Cumana tunnel. These are overlaid by the Rione Amedeo tuffs, probably the explosive eruptive products of the same magma.

This is followed by the Pianura volcano, all the southern part of which has been destroyed by later explosive eruptions, and by the erosion of the sea, which deposited the raised beach of the Lucrine Lake, ruined the south of Monte Barbaro, deposited the Starza Cliff and the raised terrace of Stabia and Castelammare.

That this volcano was the main mouth (perhaps with others) from which was derived the grey tuff of the Campania, Terra di Lavoro, &c., and the breccia beds, and to which belongs the lapillo bed near the Parco Grifeo of the Corso Vitt. Emmanuele.

That the eruptions of Roccamonfina were earlier than the eruptions of the Pianura volcano, but that Vesuvius was in great part later, because no signs of grey tuff can be met with in the Atrio section, and because the nearly complete series of Somma pumices can be seen overlying the grey tuff at Nocera.

That volcanic activity has followed a regular course southwards on the mainland of Italy.

That the yellow tuff of Posilippo, &c., is later than these deposits upon which it is superimposed, thus constituting, with the underlying segment of the Pianura volcano, the highest point near Naples, that is Camaldoli.

And that in all probability these yellow tuffs were derived, in part at least, from the Monte Barbaro and Campiglione volcano.

That any attempt to study the sequence of magmas in such a region is impossible till the whole history is carefully marked out, as shown by

the presence of basic and acid rocks amongst the ejected blocks of the piperno volcano.

That the fluoriferous metamorphism of limestone in the grey tuff occurs only where the alluvium of the buried limestone mountains enveloped fragments of that rock.

Artesian Borings and Sections at Pozzuoli.—Nine more borings have been made on the coast and in the sea at from 100m. to 150m. from the temple of Serapis. Along the sea-border, historic deposits were met with at from 11m. to 13·24m. in different borings; at 30m. from the beach historic deposits reach 9·37m.; whilst at 50m. distant, in two borings they were traversed to 21m. and 22m. At 140m., beneath 5m. of water, rounded bricks and pottery-fragments extended down to 14m. and 15·50m. respectively in two borings. Beneath the historic deposits nothing but sea-sand and mud were met with; but none of the borings extended much beyond 20m. At one point hard rock was struck at a small depth, and four other borings were made within a few yards, all touching hard rock. It is much to be regretted that none of this was detached for examination.

Nothing of any importance is demonstrated by these deposits except the very considerable deposit filled by brick, pottery, marble and other fragments, and still further confirming the depression of this region.

In cutting the new road opposite the main entrance to Sir W. Armstrong, Mitchell & Co.'s Works, a raised beach of post-Roman age was exhibited, with clean sand, many pebbles of bricks, marble and rounded fragments of mosaic. There are masses of wall fallen from the cliff-edge above as it was cut back by the sea, in which the edges, angles, &c., had been much rounded by the waves. The highest point, so far as this beach was exposed, occurs at 3·75m. above present mean sea-level.

A similar condition exists against the foot of the Villa of Cicero (*i.e.* the ruin beneath the Villa Armstrong), and west of the extremity of the valley in which the new reservoir has been constructed. There this beach reaches to nearly 5m. above mean sea-level. We have in these two localities distinct evidence of depression of the coast having reached at least 5m. lower than at present; evidence quite independent of that afforded by the temple of Serapis. At the moment that the land was at its lowest, the cliff was cut back considerably, causing the old Roman foundation to be exposed and in part to fall, to be broken up and rounded by the sea.

Close to the main entrance of the Armstrong Works the shrinking pit has been sunk to a maximum depth of about 15m., 12 of which are below sea-level. Various beds of lapillæ and pumice were met with, and near the bottom many ejected blocks of a peculiar trachyte, together with tuffs, some of each much altered by solfataric action. Most interesting was a peculiar mica-diorite (?) containing much pyrites. This rock I have occasionally met with elsewhere in the region; but it is always of rare occurrence. Professor Roth, of Berlin, who examined the specimens with me *in situ*, expressed great interest and astonishment at their occurrence. These are reserved for further study. The influx of water into the excavation was interesting, that on the side of the sea being very salt, whilst a cascade of warm mineral water flowed from a fissure on the land side, the two keeping a 20-horse pump constantly at work.

This report is but a slight sketch of the observations being carried on, which require constant and untiring attention. Even as it is, great

difficulty is often encountered in keeping pace with new exposures, borings, or sections, which are quickly built-up, choked, or otherwise effaced. In a region which is taken as a type, and upon which thousands of pages have been written, every new fact is of great general importance in elucidating many of the most important questions in dynamical geology.

In conclusion, I would express my thanks for kind assistance to Mrs. Guppy and my wife; and to Messrs. D. Roberts, Chartier, W. H. Bell, Ohlsen, A. Minozzi, and many others, in either providing me with specimens, data, or permission to visit their works.

Report of the Committee, consisting of Mr. JOHN MURRAY (Secretary), Professor CRYSTAL, Dr. A. BUCHAN, Rev. C. J. STEWARD, Hon. R. ABERCROMBY, Mr. J. Y. BUCHANAN, Mr. DAVID CUNNINGHAM, Mr. ISAAC ROBERTS, Dr. H. R. MILL, and Professor FITZGERALD, appointed to arrange an investigation of the Seasonal Variations of Temperature in Lakes, Rivers, and Estuaries in various parts of the United Kingdom in co-operation with the local societies represented on the Association.

THE work of the Committee has been confined to testing the methods for carrying on a series of systematic general observations on the temperature of the surface water in streams, lakes, estuaries, or sea. To be satisfactory such observations must be conducted simultaneously for a period of several years in as many parts of the country as possible. Volunteer observers will be necessary, and for this purpose it seems to the Committee eminently desirable to obtain the co-operation of local societies, the members of which might feel disposed to take up the work for a definite time. During the present year a commencement has been made in Scotland. There were twenty observers at work for the Committee, supplied with thermometers of a uniform pattern. Observing books ruled for date, hour, temperature of air and water, and remarks on state of river and weather, were provided, with full printed instructions at the beginning of each book for properly and uniformly making the observations. The names of observers and their stations were as follows, and we have to thank these gentlemen for their services :-

Rivers, &c.	Observers	Observations begun	Observations ended or still proceeding

List of Thermometers broken.

Cause of Breakage	Number
In transit	6
During observations	7
By accident when not in use	1
Unaccounted for	2
Total	<hr/> 16

Accurate mercurial thermometers by Adie & Wedderburn, divided on the stem and fitted into copper cases, and costing 7s. 6d. each, had previously been used; but the expense incurred by accidental breakage was great, and as many of the observers read only to quarter of a degree, it seemed unnecessary to employ such delicate instruments. A number of small mercurial thermometers with cylindrical bulbs, and provided with paper scales divided into Fahrenheit degrees from 10° to 120°, were accordingly ordered from Germany, and supplied at the rate of 15s. per dozen.

Japanned tin cases were made in Edinburgh for 13s. per dozen, including an outer tin case for travelling, the total cost being thus 2s. 4d. each. All the thermometers were compared with the Kew standard in the Chemical Laboratory of the University of Edinburgh, and the corrections noted; these rarely exceeded 0·2°, and in many cases were negligible. The instruments appear quite suited for the work, and can be replaced when broken at a trifling cost. More careful packing will practically obviate breaking in transit, and as the observers gain experience accidents occur less frequently. The observations on the Tay river system are of particular interest, as there were a number of stations on the main river, its tributaries, and feeding lakes. The curves for the various stations from December or January down to April, and in some cases to July, show distinct differences, due to the nature of the country drained by the rivers and to the altitude.

The care and regularity with which the observers in general carried out their work convinces us that it is quite practicable to carry on the observations on a large scale, and that it is desirable to extend it to England as well as to enlarge its scope in Scotland. Your Committee accordingly recommend that they be reappointed, with a grant of 50l. to be expended as follows:—

	£
Clerical assistance	20
• Observation books and circulars	15
Thermometers	10
Postages of instruments, books, &c	5
Total	<hr/> 50

The Secretary desires to say that while he has taken the general oversight of the work, the actual arrangements have been mainly carried out by Dr. H. R. Mill, assisted by Mr. John Gunn of the 'Challenger' office. The Secretary also begs to resign his position, and the Committee recommend that Dr. Mill be appointed in his place.

Several stations besides those included in the above list have been lately established, but sufficient time has not yet elapsed for the observers to have collected data sufficient to be reported upon.

A discussion of the more important results of these observations will be submitted to this meeting by Dr. Mill.

Report of the Committee, consisting of Mr. J. W. DAVIS, Mr. W. CASH, Dr. H. HICKS, Mr. G. W. LAMPLUGH, Mr. CLEMENT REID, Dr. H. WOODWARD, and Mr. T. BOYNTON, appointed for the purpose of investigating an Ancient Sea-beach near Bridlington Quay. (Drawn up by G. W. LAMPLUGH, Secretary.)

YOUR Committee report that, having obtained permission of the lord of the manor, the Rev. Farburgh Lloyd-Greame, they commenced the practical work of the exploration on June 29 last by employing labourers to carry further the excavation in the cliff at Sewerby begun last year by the Yorkshire Geological and Polytechnic Society, continuing this work through the month of July and until the end of the first week in August, with sometimes three and sometimes four workmen, under the personal supervision of Messrs. Boynton, Reid, and Lamplugh. During this time the deposits banked against the buried cliff of chalk have been wholly removed for the distance of 24 feet to a breadth of 30 feet, and partially for the further distance of 12 feet, and from the excavated material a large number of the bones and teeth of mammals have been obtained, together with remains of birds and fish and a few shells of land and marine mollusca.

Several borings have also been put down between Sewerby and Bridlington Quay, with boring rods belonging to the Geological Survey, which were kindly placed at our disposal; and in this way we have obtained important evidence as to the southward and seaward extension of the deposits and their relation to the Glacial beds.

The excavation has now been suspended because of the great thickness of incoherent sand which, as the beds recede into the cliff, is capped with heavy boulder clay, and is apt to come down in sudden falls, thus rendering dangerous any further removal of the old beach unless a large mass of the superficial beds were first thrown off; and this, with the funds at their disposal, your Committee have not been able to undertake, and are, indeed, doubtful of the expediency of doing. A short gallery has, however, been driven along the face of the old cliff for about 12 feet beyond the open working.

The following account of the deposits will show the results obtained up to the present time.

History and Literature.—These deposits, for which we propose the name of 'the Sewerby Cliff-beds,' have nearly always been hidden in the cliff-foot under a long talus of drift slipped from above, and remained undiscovered until the winter of 1883-4, when your reporter's attention was drawn to them by a fisherman, who had noticed two bones in a portion of the cliff recently laid bare by storms. The writer knew that the tusk of an elephant had been found some years before near this place, but until this time he could not find the bed from which it had been obtained, though in his examination of the section he noticed the abruptness with which the chalk ended, and, in a paper on the Speeton Shell-bed,¹ mentioned the discovery of the tusk and suggested that it might have come from some bed below the drift.

It was at first believed that the two bones formed part of a skeleton,

¹ *Geological Magazine*, Dec. II. vol. viii. p. 174.

but when they were excavated by the writer's friend, Mr. J. R. Mortimer, they proved to be disconnected and isolated.

No further investigation was made at this time, but a few months later one of this Committee, Mr. C. Reid, who was carrying out the work of the Geological Survey in Holderness, had the beds pointed out to him. Recognising the importance of the section, he had a trench cut into the cliff to show the sequence of the deposits, and published an account of them in 1835 in his Survey Memoir on 'Holderness' (pp. 47 to 49), this being, so far as we know, the earliest printed description.

A short reference was also made to the beds in the Sheet Memoir on Bridlington Bay, by J. R. Dakyns and C. Fox-Strangways, p. 1, published in the same year.

Mr. Reid having strongly recommended further investigation, the Council of the Yorkshire Geological and Polytechnic Society undertook the work, granting the sum of 10*l.* towards the expenses of an excavation which was carried out last summer under the superintendence of Mr. T. Boynton and your reporter. It was then shown that the deposits rested on a floor of solid chalk, and had no Glacial beds below them; and that the whole of the boulder-clay series present in the recent cliff above the chalk rested unconformably on these beds and cut them out. From this excavation a large number of bones and teeth and other remains were obtained, which were deposited in the museum of the Yorkshire Philosophical Society at York. A paper on the results of this excavation by Mr. J. W. Davis was read at the last meeting of the Association, and an abstract of this is printed in the last 'Annual Report,' p. 694.

A detailed account of the beds with a list of the fossils as then determined is contained in the report sent in to the Yorkshire Geological and Polytechnic Society by the writer, which was printed in their 'Proceedings' for last year (p. 381), and is illustrated by a woodcut section and lithograph sketch.

These are the only references known to your reporter.

The Ancient Cliff: its Position and Relation to the present Shore-line.—Flamborough Head has long existed as a feature on the coast line of Yorkshire, for, as Professor Phillips long ago pointed out, its main features were already carved out in Pre-Glacial times. It consists of a mass of hard chalk, everywhere covered with Glacial deposits varying very greatly in thickness. The middle portion of the chalk contains much flint, and is a massive well-knit rock, while the upper and lower parts have no flint, and are softer and more fissile and shaken, so as to yield more readily to the sea; and to this difference in the rock the shape of the headland is largely due, for where the southerly dip brings the Upper Chalk to the beach on the south side of the promontory, the cliff line recedes; and where, on the other hand, the Lower Chalk rises above the shore on the north side, it also is attacked and suffers; while where the cliff from top to bottom consists of the massive flinty rock, there are many signs that the denudation goes on very slowly.

The drift-covering hides up many inequalities of the old rock surface, and makes others of its own, so that, were it not for the continuous cliff sections, we should be greatly deceived as to the shape of the ancient land.

This is strikingly exemplified in the cliff at Sewerby, on the south side of the Head, about four miles west of the easternmost point, and about one mile east from Bridlington Quay.

* Here, near the Park, the cliff is about 75 feet high, the lower 40 feet,

consisting of chalk, which is overlain by about 35 feet of Glacial beds; but, when we go a few yards to the southward, the chalk is seen to end abruptly in a cliff that is quite vertical, and in some places overhanging; and beyond this point no solid chalk is seen in the section. On the surface this bold feature is so well masked by the thickening of the drifts that its presence would not be suspected. There is, indeed, an obscure line to be traced for a short distance across the fields, where the ground sinks for a few feet, but this is quite uncertain, and is probably nothing more than a bank of the uppermost gravel, such as is common in the neighbourhood.

When this cliff formed part of the ancient shore-line, though the sea stood at somewhere about its present level, the physical geography of the country must have been quite different.

The headland must then have been a far more prominent feature than it is to-day, that rubble heap of drift which we call Holderness having then no existence, except as a shallow sea-bottom, across which throughout Yorkshire, and probably throughout Lincolnshire also, the waves washed till they reached the eastern foot of the Wolds. There is evidence, moreover, that the sea has reached into the hollow ground on the northern side of the headland, now occupied by the drift, since at Speeton an estuarine shell-bed is found below the Glacial series, resting on the Speeton Clay, at a short distance from the edge of the chalk escarpment. This bed, however, is at least 85 feet above high-water mark, and is, therefore, probably not exactly contemporaneous with the Sewerby Cliff-beds.

It is where the present shore-line intersects this ancient shore-line at Sewerby that our excavation has been carried out, and as the lines cross each other at a low angle—the recent beach striking N.E. and S.W. nearly, while the old cliff strikes about E.N.E. and W.S.W.—we have been able to work for some distance along the denudation-slope of the recent cliff, where the ancient beach deposits are stripped of their covering of boulder clay; but the gradual recession of the old cliff inland has brought us so far into the slope that this mode of working can no longer be carried on.

The face of chalk in the old cliff above the old tide-level is everywhere smoothed and rounded in a manner strikingly different from the angular mode of weathering of the recent cliff adjoining.

Against it are banked the deposits we have excavated, in the order now to be described.

The Old Sea-beach.—At the bottom, resting on the terraced 'scaur' of the chalk, is a sea-beach composed of water-worn chalk pebbles of all sizes, from fine gravel to large stones over a foot in diameter. These are nearly always of the flat oval form that characterises this chalk as a beach material. Many are perforated by the borings of *Pholas*, *Saxicava* and *Cliona*, which shows that an uncovered scaur of chalk has extended at least to near low-water mark. Besides chalk there are also pebbles of grey flint, some rather large in size, of the kind found in the Middle Chalk on the north side of the headland. The chalk in the immediate neighbourhood has no flint, and these pebbles must have drifted not less than four or five miles. They are more plentiful than in the recent beach at this place.

The old beach also contains a few pebbles that are not of local origin. These are comparatively very rare, but we have this year found more of such stones, and some of larger size, than in our last year's excavation, the

largest being a boulder of basalt measuring 12 in. \times 5 \times 3, and another of porphyrite 7 in. \times 4 \times 3. The proportion of these stones evidently varies in different parts of the beach, being very low indeed close to the cliff-foot, but rising higher as we work outwards and downwards. Nowhere, however, have we found them to form more than a very fractional percentage of the whole.

The most plentiful rock among these strangers is a brown or black laminated bituminous shale, with obscure traces of plants and other fossils. This shale is very light, and when perfectly dry will float, so that it may have drifted along the coast into its present position. Its origin is doubtful, but it is not unlike some of the shales in the estuarine Oolites of the Scarborough district. Other pebbles are of basalt, granite, quartz of various colours, porphyrite, &c., the whole forming an assemblage not strikingly different from that of our Glacial beds. Some of these pebbles are well rounded, but others do not seem to have been rolling long on the beach and are almost subangular. The presence of these pebbles is a fact of much importance, since we shall be able to show that the Cliff-beds underlie the oldest boulder clay known in Yorkshire, and these pebbles are the first indications we have had of the existence of glacial conditions in still earlier times. It is evident, however, that they have not been derived from the sub-aerial waste of any Glacial beds capping the old cliff, for in that case we should have found them plentifully in the rain-wash from the cliff presently to be described; nor are they, in the opinion of the writer, present in sufficient numbers to indicate the waste of pre-existing Glacial beds anywhere in the immediate neighbourhood, though they may have come from the denudation of such beds at a distance.

Here and there among the gravel and stones of the beach occur the bones of mammals, birds, and fish, and, still more rarely, shells of the periwinkle, oyster, and other molluscs. These remains are nearly always in a bad state of preservation, being often crushed into small fragments (as are also many of the chalk pebbles) by the settling of the beds, perhaps under the weight of the ice in the extreme Glacial period; and they are, besides, so softened by the percolating waters that when first found they may often be rubbed into a paste between the finger and thumb. When exposed to the air, however, they harden, and occasionally when a bone has lain close under the sheltering cliff, or between the larger stones of the beach, the pressure has been so far removed that they may be got out in fair condition, and then, when gelatinised and repaired, they make good museum specimens.

The thickness of this beach close to the old cliff is from 3 to 5 feet, but it thickens as we pass down the ledges of the chalk floor on which it rests, so that at the outer edge of our trench, 30 feet from the cliff, it was over 7 feet thick, and in a section we cut further south, where we struck the beds still further from the cliff face, we passed through 9 feet of beach-shingle and sand before reaching the solid chalk. As it thickens it becomes more sandy, so that, though close to the cliff it consists of nothing but loose stones, in passing outwards and downwards we find much sand mixed with the stones, while in the above-mentioned cutting thick seams of pure sand are reached. In this respect the old beach is an exact counterpart of the recent beach at this place, in which there is a similar arrangement of rough loose shingle under the cliff-foot, passing outwards into a flat sandy shore.

The chalk floor close to the cliff is at about the level of the present high-water mark, so that the top of the beach here is decidedly above that level, though not so far above but that a stormy sea and heavy tide might yet overwhelm it. Now, though on a long sloping shore the beach material is usually flung to the highest point that the tide reaches, against a vertical cliff the sea nearly always rises higher than its shingle, and we therefore think that when the old beach was formed the land stood slightly higher than at present. It is remarkable, however, how slight is the difference in level between these two beaches, separated as they are by such a wide interval of time, and by such a cycle of changes as the Glacial period. Nor, were it not for the comparative scarcity of foreign pebbles in the former, is there much difference in appearance between the ancient and the modern beach. The chalk pebbles in both are worn into the same shapes and bored in the same way, and the few shells that are to be found in either are of the same species. It is not until we come to examine the bones of the mammals that we find the effect of the lapse of time. The elephant, rhinoceros, hippopotamus, and elk have gone, but the periwinkle and oyster remain.

The Land-surface.—Close at the cliff-foot the beach is covered by a deposit of marly clay with angular and subangular masses of fallen chalk and streaks of drifted sand, that has evidently accumulated sub-aerially as talus and rain-wash. This deposit is about 5 feet thick where it touches the cliff, but does not extend far outwards, dovetailing rapidly into the blown-sand, so that no trace of it is to be found at more than 20 feet from the cliff.

Bones occasionally occur in this bed, generally in the lower part of it, and we also found in a seam of yellow earthy clay many small land-shells and obscure traces of vegetation along with two or three teeth of vole and fragments of birds' bones.

It contains no marine remains whatever, and no sea-worn pebbles. The sea had evidently quite abandoned the cliff when this bed was formed, though the character of the junction with the old beach shows that this abandonment took place gradually. Possibly, with no change of level, the sand dunes may have accumulated so as to shut out the sea, and this deposit may then have formed in the hollow between them and the cliff. A few very small angular fragments of grey flint occur in the bed (which are noteworthy, as there is no flint in the cliff above), and we also occasionally found small rounded bean-like pebbles of ancient rocks. These, as one of our Committee pointed out, have probably drifted up from the sea-shore of the period entangled in rolling balls of seaweed, such as travel with the wind on most sandy shores.

This bed, though so limited in breadth, has extended along the whole length of cliff already exposed and shows no signs of thinning, so that it is probably not, as we at first thought probable, a local talus-heap but a regular accumulation extending laterally along the cliff-foot.

We thought this our most promising ground, somewhat analogous to a 'cave earth' formed in the open; but in our recent excavations it has disappointed us, our finds in this part of the series being fewer and poorer than those of last year.

The Blown-sands.—A great mass of clean yellow sand, without admixture save for a few blocks of fallen chalk and an occasional bone, overlies the rain-wash, and also overlaps it so as to rest directly on the old beach at the outer edge of our excavation. This reaches quite up to

the top of the old cliff, and has no doubt once extended over its brow, but is now cut off there by the chalky rubble at the base of the drifts. It is quite 25 feet thick in one part of our excavation, and seems to thicken as the cliff recedes inland. It frequently exhibits fine cross-bedding. The upper 15 feet seems to be quite unfossiliferous; but lower down, at about the level of the rain-wash, we found a few bones, these being usually far better preserved than those found in the other beds. We have already referred to the anxiety which this sand caused us from its tendency to suddenly collapse and slide in on us; this happened even on a long low slope. It has evidently been accumulated under the shelter of the cliffs by the wind, and the cliff-face behind it has been beautifully smoothed and rounded by the drifting of its wind-driven particles. The same feature is seen on the cliff-face behind the rain-wash, but stops short at the old beach where the weathering takes a different form. This rounded surface is quite characteristic of the old cliff, and, as already mentioned, is in marked contrast with the adjoining recent cliff, whose outline is splintered and angular through the action of the winter frosts. This feature points to a long-continued prevalence of strong winds from the south or south-east, unaccompanied by frost, that have driven up the sand from a wide sandy shore lying to the southward, so as to form great dunes overtopping the cliff.

The Fossils.—A list of the species that have been identified from among the fossils found in the Cliff-beds is given on the opposite page. We are indebted to Messrs. E. T. Newton, C. Reid, and H. M. Platnauer for the determinations.

The asterisks in the columns denote in which bed the fossil was found.

In the old beach the bones are generally water-worn and rounded, and also often in the rain-wash; but in the blown-sand they are frequently quite unworn, and in a few instances have their finer angles and delicate muscular markings beautifully preserved.

Careful search was made for any evidence of man's presence, but with negative results, for among the large number of flints examined none showed any certain signs of having been worked.

The Glacial Deposits, and their Relation to the Cliff-beds.—We have accounted for about 40 feet of the recent cliff at Sewerby. The remaining 35 feet consists of Glacial beds, which it will now be necessary to describe.

The Chalk-rubble.—At the base of the drifts, resting directly on the chalk on the old cliff, we find a variable thickness of chalk-rubble or gravel, made up of angular and sub-angular fragments of chalk, generally of small size, often partially cemented together by a clayey matrix. This bed is found at the base of the drifts nearly everywhere on Flambro' Head, and overlaps the solid chalk, passing down on the north side at Speeton for some distance over the Speeton Clays. Small drift-pebbles may occasionally be found in it, but these are rare. In appearance it is such a bed as might result from the sub-aerial wash, and weathering of the chalk, and this origin is generally assigned to it. But whatever the mode of its accumulation, its connection with the overlying Glacial beds is very close. No organic remains have yet been found in it.

In our section this chalk-rubble is seen to pass off from the top of the old cliff and to continue over the blown-sands with very little immediate change of level. Before leaving the chalk it is about one foot thick, though

Fossils from the Sewerby Cliff-beds	Old Beach	Rain Wash	Blown-sand	Remarks
<i>Elephas</i> (? <i>primigenius</i> , Blum.). The Mammoth	—	—	*	Several molars from the old beach and two from the blown-sand. One molar only seems to belong to the Mammoth, the others being referable to <i>E. antiquus</i> . Also some broken limb-bones, badly preserved, in the old beach.
<i>Elephas antiquus</i> , Falc. Elephant	*	—	—	
<i>Rhinoceros</i> , probably <i>leptorhinus</i> , Cuv. Rhinoceros	* !	—	—	Several molars and portion of a lower jaw; possibly also other bones.

<i>Saxicava</i>	*	—	—	

its exact thickness is difficult to measure, since there is at this place no clear line between it and the shaken chalk of the cliff-top; but where it extends over the blown-sands it thins to 3 or 4 inches, and in one place seems to disappear for a short space altogether, being apparently cut out by the overlying boulder clay. Soon after leaving the chalk cliff it begins to descend, thickening rapidly in doing so, and cutting into the blown-sand. Thus, at 50 yards from our excavation it has sunk so that its base is only about 20 feet above sea-level, it is composed of finer material, and its thickness has increased to 11½ feet. Beyond this the cliff section seemed to show over 25 feet of this material at the bottom; but when we commenced

to cut a trench into it, thinking to strike the Cliff-beds somewhere behind it, we soon found that the lower part of the section was not the chalk-rubble but a talus slope from that bed covering the blown-sands, and that the thickness of the rubble here was not more than 12 feet. A second trench 80 yards south of our excavation gave similar results, though the base of the chalk-rubble had now sunk to about 6 feet above high-water mark, with a corresponding diminution in the thickness of the blown-sands. It was in this trench that we went through 9 feet of old beach and reached the solid chalk floor. Seventy yards further south, though the chalk-rubble is still 13 feet thick in the cliff, its base has reached the sea-level, and a short boring was necessary to get below it. This boring showed us that there is here about 4 feet of the bed below high-water mark, and that it rests directly upon a sea-beach of sand with rolled pebbles, the blown-sands having quite disappeared.

We put down another bore into this bed 30 yards further south, starting in the cliff-foot about 2 feet below the top of the bed, and here we bored into it for 21 feet without reaching its base. The same result followed a boring on the beach 60 yards nearer Bridlington, where the upper surface of the bed has sunk below high-water mark and the cliff-foot is held by the overlying boulder clay. Here we went through 23 feet of chalk-rubble, with sandy and clayey seams full of water, without reaching its base. One of the clay seams passed through in this boring somewhat resembled a boulder clay in appearance, and, though the samples brought up by the auger were not sufficient for us to decide whether this was indeed a boulder-clay, there are other reasons for thinking that the rubble is partly contemporaneous with the Basement boulder clay, and that there is in places a certain amount of dovetailing between them.

The Basement Boulder Clay.—The cliff section for half a mile southward from our excavation is nearly always hidden, except just at the top, by a long slope of slipped clay and gravel, and is not often washed by the sea; but, by a fortunate combination of circumstances, during last March high tides and heavy seas swept the base of this cliff clearer than it has been for ten or fifteen years, and also laid bare a long strip of foreshore stretching at one time or another as far as the sea defences of Bridlington Quay. These exposures enabled the writer to trace the lowest boulder clay of the cliff at Sewerby into the 'Shelly' or 'Basement' boulder clay of Bridlington Quay.

The clay changes considerably in character in this distance, but was traced continuously northward from opposite Sands Cottage, where it is a dark greenish boulder clay of the normal 'Basement' type, full of shell fragments, to the cliff near our excavation, where it is rather different in colour, is more earthy, has few or no shells and also few boulders, and passes over (and possibly, as already mentioned, partly into) the chalk-rubble just described. As it follows the rise of that bed over the blown-sands to the top of the chalk cliff, it is reduced to a thickness of only 8 feet, though there is over 25 feet of it at Bridlington Quay. Above the chalk it may readily be traced along the cliff for two miles to Danes' Dyke, where there is so much splitting up of the beds that it is more difficult to follow; but there is every reason for believing that it continues beyond, and forms the lowest boulder clay almost everywhere on the headland. Where its base is seen the lowest two or three inches are generally distinctly stratified, with the bedding planes marked by thin films of silty sand; but, except in a few places, this character dies

out upwards and the remainder of the clay generally forms a solid mass, broken only by the occurrence here and there of irregular pockets of sand, gravel, and clay that seem to have been caught up and included in it. This inclusion of other beds is its most characteristic feature, and one that is sure to be found wherever the clay can be traced for any distance. In the neighbourhood of our section these patches are of chalk-rubble or of clayey silt and sand; but further east on the headland, near the lighthouses, the lowest boulder clay (almost certainly this Basement clay) includes transported masses of Speeton clay mixed with some red chalk, while at Bridlington Quay and elsewhere some of the patches of clay and sand which it encircles are richly fossiliferous, and form the deposit long known as 'the Bridlington Crag.' These shelly patches contain a peculiarly Arctic molluscan fauna of great richness and variety, and are the fragments of an old sea-bottom formed under extremely glacial conditions.

Until the exposures of last spring the continuity of this shelly Basement clay with the boulder clay covering the Cliff-beds was extremely doubtful, and the writer was inclined to believe, for reasons that will presently be given, that the Basement clay was not represented in our section, or was represented only by the chalk-rubble, but the new evidence has determined this point.

The upper limit of the Basement clay in our section is well marked by a thin seam of fine shingle and sand about four inches thick. This parting, though here so slight, if followed southward for a few hundred yards, is found to develop into a thick bed of finely laminated elastic clay with a seam of fine gravel above and below it, that forms for some distance a well-marked horizon.

This laminated clay contains no organic remains and no pebbles. It seems to have been accumulated in the hollows of an uneven surface of the Basement clay, and is not found much above high-water mark.

The Purple Clay.—Next in the Sewerby section comes a thick homogeneous mass (18 feet) of tough brownish-coloured boulder clay that is rather more stony than the Basement clay, and not so earthy in texture. No dividing line has been found in it in this section; but if the clay be followed southward for a short distance, it is found to split into an upper and a lower division that are separated by the intervention of a variable bed of sand and gravel that often shows contortions, and this division may be traced through the greater part of Holderness.

It was the absence of this line, and the consequent presence of only two beds of boulder clay over the chalk, instead of the three seen so well at Bridlington Quay, that led the writer and others to doubt whether the Basement clay passed up over the chalk in the cliff.

The Sewerby Gravel.—A well stratified bed of chalky gravel 10 feet thick caps the section, and may be traced southward along the cliff-top nearly to Bridlington Quay.

This is known as the Sewerby Gravel, and, though rather newer than the boulder clays, it probably dates back to the time when the ice was retreating, and can scarcely be called Post-Glacial. But through it a passage to more recent times may be traced, by way of certain low-level gravels of fresh-water origin with which it seems to be connected near Bridlington Quay, and which in turn lead up to the fresh-water marls that lie in the hollows on either side of the town, whose formation has probably gone on till comparatively recent times.

Age of the Buried Cliff-beds.—In your reporter's communication to

the Yorkshire Geol. and P. Society on these beds, he suggested that they might be called *Pre-Glacial*, since they were so distinctly older than the Basement clay, which has been regarded (perhaps without much evidence) as the oldest bed of the Yorkshire Glacial deposits. But it has since been suggested that the term *Sub-Glacial* would better indicate this relationship without inference as to the age, and our recent discovery of foreign pebbles in greater numbers and of larger size than before shows the wisdom of this suggestion.

While the presence of a few travelled pebbles is scarcely alone sufficient evidence of the Glacial age of the beds, since such pebbles occur in beds that are allowed to be *Pre-Glacial*; as, for example, in the Norfolk Forest-bed series; yet the fauna, as at present determined, lends no countenance to the view that the beds are actually *Pre-Glacial*, though, on the other hand, it contains nothing that is decisively against this view. A large number of the bones obtained, however, are yet in an indeterminate condition, and we hope that when they shall have been repaired and examined they may yield closer results.

The Basement clay contains so much evidence of the destruction of an old sea-bottom at some distance from the shore, that the idea naturally arises that the beach we have been examining may have formed the shoreline of that period. But the evidence of their respective faunas is quite opposed to this, for the Bridlington shells denote a very cold climate—not quite but nearly the coldest we have evidence for in Great Britain—whereas the old beach, with its hippopotamus and oysters and its unfrosted cliff-face, indicates a climate, if anything, warmer than we enjoy at present.

Of course it may be urged that, as the shell-beds of the Basement clay are not in place, they may have been carried for long distances, and are not evidence for an extreme climate in their present resting-place. But even if far transported they must still have been formed somewhere within the North Sea basin, and the presence of such a fauna anywhere within so shallow and limited an area seems hardly compatible with the contemporaneous occurrence of a warm climate on its shores. So that the correlation of the old beach with the shell-beds of the Basement clay seems an improbable one.

The presence of foreign pebbles in the beach is certainly evidence for the existence of ice in some form, either during the formation of the beach or prior to it; but unfortunately we cannot say whether these have been derived from pre-existing Glacial beds somewhere within reach of the sea, or have come more directly through the stranding of small drifting bergs or coast-ice.

Independently of its fauna, the Basement clay is in itself the proof of a very severe climate, and shows a set of conditions that could not suddenly have arisen. Possibly the minor oscillations that may have occurred during the gradual approach of the great Glacial period, before the maximum cold set in, may account for the somewhat contradictory evidence of these beds.

It is unfortunate that we have been able to recover so small a portion of the fauna which must have existed at that time. Our list is evidently a mere fragment, and both on land and sea there has undoubtedly been abundant and varied life.

But the circumstances are not favourable. For sea-shells we have had only the highest and roughest portion of an old beach to explore,
1888.

wherein we could not in any case have expected to find many shells, while here the conditions have been so unfavourable for their preservation that even such strong shells as *Littorina* are only imperfectly preserved and crumble with a touch. Similarly with the land-shells, our collecting ground has been what at one time was a range of barren shifting sand-hills whereon the fauna was probably always very limited; and for the preservation of the specimens we possess we are indebted to the clayey matrix of one particular seam not much over an inch thick. So with the mammalia. We have not reached their dens or haunts, but have chiefly to rely for our specimens on the bones sporadically scattered along a sea-beach; and under these circumstances it is not surprising that we have not been able to identify the carnivore whose teeth-marks we have found on some of the bones, nor to specifically determine some of the other animals. Indeed it is remarkable enough that under such conditions we have found so much; and we are inclined to think that the presence at that period of a river in the Main Wold valley, which opens to the sea at Bridlington Quay, may have caused slightly estuarine conditions to prevail over this part of the old bay, and so have brought about the comparative abundance of animal remains in the beach and the presence of the hippopotamus.

Relation to other Deposits.—These Cliff-beds cannot safely be correlated with any other deposit known in Yorkshire. Their nearest analogue is the estuarine shell-bed at Speeton mentioned in an earlier part of this report; but, as was before pointed out, the difference of level between them is so considerable that it is unlikely they have been exactly contemporaneous.

In several other places on Flamborough Head the coast section reveals steep bluffs of chalk below the drifts, but in no case except this have any fossiliferous deposits been found in connection with them, and they seem in most cases not to be sea-cliffs, but steep valley walls. At Flamborough South Landing under one of these bluffs there is an accumulation of rough pebbles somewhat resembling a beach, but it differs from the Sewerby beach in the presence of a multitude of foreign stones and in the absence of *Pholas*-bored pebbles or fossils of any kind.

Your Committee ask to be re-appointed for the purpose of completing the repair and determination of the fossils already obtained, but do not propose at present to ask for a renewal of the grant.

Report of the Committee, consisting of Professor LANKESTER, Professor MILNES MARSHALL, Mr. SEDGWICK, and Mr. G. H. FOWLER (Secretary), appointed for the purpose of investigating the Development of the Oviduct and connected structures in certain fresh-water Teleostei.

WITH regard to the grant made, I regret to say that I have been unable to make use of it. For various reasons the perch was selected as the most suitable subject for investigation, and arrangements were made with Mr. Armistead, of the Solway Fisheries, for supplies of ova and fry. These, however, unfortunately, altogether broke down, and that at a time when the spawning season was just over, and when, consequently, no further attempts could be made till the ensuing spring. The

grant of 15*l.* is still unbroken, and if the Committee should be disposed to continue it, different arrangements next year would probably lead to a more favourable result.

Third Report of the Committee, consisting of Professors ARMSTRONG, LODGE, Sir WILLIAM THOMSON, Lord RAYLEIGH, FITZGERALD, J. J. THOMSON, SCHUSTER, POYNTING, CRUM BROWN, RAMSAY, FRANKLAND, TILDEN, HARTLEY, S. P. THOMPSON, MCLEOD, ROBERTS-AUSTEN, RÜCKER, REINOLD, CAREY FOSTER, and H. B. DIXON, Captain ABNEY, Drs. GLADSTONE, HOPKINSON, and FLEMING, and Messrs. CROOKES, SHELFORD BIDWELL, W. N. SHAW, J. LARMOR, J. T. BOTTOMLEY, R. T. GLAZEBROOK, J. BROWN, E. J. LOVE, and JOHN M. THOMSON, appointed for the purpose of considering the subject of Electrolysis in its Physical and Chemical Bearings.

DURING the past year work has been done by the Committee as follows:—

Prof. Fitzgerald and Mr. Trouton have continued their investigation into the accuracy of Ohm's law in electrolytes, with the result that the coefficient h in $e=rc(1-hc^2)$ is now known to be less than 3×10^{-6} in sulphate of copper solution. Their communication is annexed in continuation of their previous contributions on the same subject as given in the 1886 Report, p. 312, and in the 1887 Report, p. 345.

Lord Rayleigh has experimentally examined the question whether the velocity of light through an electrolyte is affected by the passage of an electric current in the same direction, and his account of the experiment and of its result is annexed.

Dr. Gladstone and Mr. Hibbert have experimented on the mode of conduction of alloys and solid sulphides, and their paper is appended to this report.

Dr. Armstrong has been preparing some pure selenium, with the view of examining its conductivity; and Mr. Crompton, in his laboratory, is engaged in determining the resistance of sulphuric acid of various strengths at different temperatures, with the object of applying to the results Mendelejeff's theory of solution, as explained and partially reported in the 'Transactions of the Chemical Society' for January 1888.

Mr. Shaw is continuing the drawing up of his report on recent progress in the whole subject of electrolysis.

Prof. Willard Gibbs has sent a letter to the Secretary, replying to some observations made in last year's report concerning a communication with which he had previously favoured the Committee: see Report, 1886, p. 388; and 1887, p. 340. This letter is printed below.

Prof. Clausius has sent a letter to the Secretary with respect to the nomenclature often adopted in England for the dissociation hypothesis of electrolytic conduction, which, on the Continent, is known by his name alone. The Committee record the deep regret with which they have quite recently heard of his death.

The paper by Prof. von Helmholtz, 'Further Researches respecting the Electrolysis of Water,' as translated and communicated to the

Section last year, has appeared in the Physical Society's collection and reprint of papers.

The Committee may also call attention to a paper by Prof. Horace Lamb, 'On the Theory of Electric Endosmose and Other Allied Phenomena,' printed *in extenso* in the Manchester Volume, 1887, p. 495.

Mr. Fitzpatrick's paper on Electrolytic Conductivity, communicated to the Section last year, has been printed in the 'Philosophical Magazine' for November 1887.

Bulletin No. 36 of the United States Geological Survey, 'On the Subsidence of Fine Solid Particles in Liquids,' by Carl Barus, has been sent from the Government printing-office at Washington to the Secretary. It is interesting as containing an application of electrolysis to accelerate the settling of turbidity; and Dr. Gladstone's paper last year (1887 Report, p. 344), 'On the Action of an Electric Current in hastening the Formation of Lagging Compounds,' may be mentioned in connection with it.

Dr. Arrhenius has transmitted to the Secretaries various reprints bearing on the dissociation hypothesis of electrolytic conduction and other matters, and one manuscript, which is appended to this Report.

Dr. Richarz has also sent some papers, one of which, not being elsewhere published, is annexed.

The work of Prof. Rowland and Mr. Bell, 'On the Effect of a Magnet on Chemical Action,' communicated verbally to the Section last year at Manchester, has now appeared in the 'American Journal of Science' for July 1888, and in the 'Philosophical Magazine' for August 1888.

The Committee, at a previous meeting, instructed their Secretary to endeavour to obtain the translation and publication of some of von Helmholtz's papers. They have seen with great satisfaction that the action of the Physical Society of London has rendered further motion on their part in this direction unnecessary, and they congratulate Prof. Carey Foster on the volume which has appeared under his supervision.

The most remarkable experimental result within the scope of the Committee to be recorded in the past year is that obtained by Dr. Hertz, subsequently confirmed and further investigated by E. Wiedemann and Ebert, Hallwachs, and Arrhenius, on the effect of ultra-violet light in making air or any gas conducting, and especially in breaking down the transition resistance or obstructive film at the cathode of an electric sparking arrangement. The experiment is exceedingly easy to perform with either a small induction coil or a Voss or Wimshurst machine, the light used being either the light of another spark, or of magnesium wire, or of an arc lamp. The length of a short spark may be trebled by mere illumination with ultra-violet light: the difference of potential between the terminals being kept constant.

The fact that the effective cause of this phenomenon is not the long waves of ordinary electric oscillation, but is the light which most nearly corresponds in frequency to electric oscillation in bodies the size of molecules, suggests some chemical or dissociation cause of the effect.

Of the 50% grant made to the Committee last year, 30% has been drawn and spent, partly in a rapid vibrator for the use of those experimenting on Ohm's law, partly in expenses connected with the preparation of pure selenium, and the rest (some 15%) in separate copies, printing, and postage. It is proposed to ask for reappointment, with the sum which has now lapsed renewed.

*On the Accuracy of Ohm's Law in Electrolytes.**By Professor FITZGERALD and F. TROUTON.*

Experiments have been made with the faster fork alluded to in last year's report, with the result of bringing the determination to about twice the degree of refinement then mentioned as attained, or ' h ' to be less than 3×10^{-6} . The rate of this fork (about 290 vibrations per second) is nearly twice that of the previously employed fork (160 per second). From the experiment described below the possible increase in refinement obtainable by doubling the rate appears to be about fourfold, or twice that obtained.

Considering that the difficulties of working increase greatly with the rate of the fork, it was thought more advisable for the further prosecution of the investigation to try some other method of breaking the contacts than to prepare a still faster fork.

A commutation arrangement attached to the spindle of a small magneto has been employed with fairly satisfactory results. As great a refinement, however, has not yet been reached with it as was attained with the fork method,¹ chiefly through the difficulties connected with running the magneto uniformly; but we hope soon to have storage cells in the laboratory, and thus to get over this difficulty.

The magneto arrangement, however, on account of the facilities for changing the speed, was found admirably adapted for confirming the supposition that the observed deviation from Ohm's law is due to 'heating effects,' for the deviation always tended to disappear as the speed of contact-breaking was gradually increased; also for investigating the manner in which the minimum value of ' h ' obtainable varies with the speed of contact-breaking. This was found to be, approximately, inversely as the square of the speed.

Is the Velocity of Light in an Electrolytic Liquid influenced by an Electric Current in the direction of propagation? By Lord RAYLEIGH, Sec.R.S.

The question here proposed has been considered by Roiti (Pogg. 'Ann.' 150, p. 164, 1873) and by Zecher ('Rep. de Phys' 20, p. 151, 1884).² My experiments were made in ignorance of the work of these observers, and the results would scarcely be worth recording were it not that the examination seems to have been pushed further than hitherto. It may be well to say at once that the result is negative.

The interference fringes were produced by the method of Michelson, as used in his important investigation respecting 'The Influence of Motion of the Medium upon the Velocity of Light.'³ The incident ray ab meets a half-silvered surface at b , by which part of the light is reflected and part is transmitted. The reflected ray follows the course $abcdefbg$, being in all twice reflected at b . The transmitted ray takes the course $abfedcbg$, being twice transmitted at b . These rays, having pursued identical paths, are in a condition to form the centre of a system of fringes, however long and far apart may be the courses cd , ef .

There is here nothing to distinguish the ray ab from a neighbouring parallel ray. The incident plane wave-front perpendicular to ab gives rise eventually to two coincident wave-fronts perpendicular to bg . With a wave incident in another direction the case is different. The two emergent wave-fronts remain, indeed, necessarily parallel, both having experienced an even number of reflections (four and six). But there will exist in general a relative retardation, of amount (for wave-fronts perpendicular to the plane of the diagram) proportional to the deviation from the principal wave-front. Hence, if the incident light comes in all directions, a

¹ A very unsatisfactory experiment with the magneto at a speed of about 400 vibrations per second gave, as the value of h , 1.25×10^{-6} .

² Mr. Wilberforce has experimented upon displacement currents in a dielectric (*Camb. Phil. Trans.* t. xiv. p. 170, 1887).

³ *Am. Journ.* xxxi. p. 377, 1886.

telescope at g , focussed for infinitely distant objects, reveals a system of interference bands, whose direction should be vertical, if the adjustments could be perfectly carried out in the manner intended.

The success of the method does not require the complete symmetry of the diagram. If the reflections at d , e are effected by a right-angled prism, it is necessary that cd , fe be parallel to one another, but not that they be parallel to the surface b . Supposing all the surfaces to remain vertical in any case, the positions of b , f , and the incident ray ab may be chosen arbitrarily. If the distance de between the parallel courses is not closely prescribed, one adjustment by rotation of the mirror c will suffice. In my experiments the optical parts were mounted upon a large iron plate, so that the movable pieces c , de could be shifted without loss of level. The incident ray ab was defined by a small hole near the paraffin lamp which served as a source of light, and by the centre of a moderately large circular aperture perforated in a screen and illuminated when necessary with a candle. The mirror c was then rotated until the rays cd , fe were parallel. This was tested by observing the equality of their mutual distances near the extremities of their course.

If the distance between the parallel rays is prescribed, the adjustment is more troublesome. The line fe being fixed, sights are laid down defining the desired position of cd . These sights, as well as those before referred to defining the incident ray, have now to be brought to apparent superposition as seen by an eye looking along dc . For this purpose *two* conditions have to be satisfied by, and two motions must be provided for, the mirror c . One of these should be a movement of rotation, and the other of translation in a direction nearly perpendicular to the plane of the mirror. Thus the mounting may consist of a circular turntable resting upon the iron plate, the curved edge of which is guided by the sides of a V, cut out of a flat piece of metal and clamped to the plate. In each position of the V the angular motions are easily swept over, and the double adjustment is effected without much difficulty. When the parallelism of the rays is secured, the insertion of the reflecting prism is all that remains. The adjustment of this is best effected with the eye at the observing telescope, which at this stage should be focussed upon the small aperture in the neighbourhood of the flame. By a motion of the prism parallel to its hypotenuse the two images are brought to coincidence,¹ and then the bands appear, if not at once, when the telescope is accommodated for infinitely distant objects.

¹ It should be noticed that if the object were at infinity, or if with the aid of a collimating lens an image of it were thrown to infinity, the two images as seen focussed through the telescope would overlap in any case; for it may be proved that, whatever may be the positions of the five reflecting surfaces, the two emergent rays, corresponding to any incident ray, are necessarily parallel.

The half-silvered central plate would be at its best if it reflected light of the same intensity as it transmits. I have generally found the reflection on the side next the air more powerful than upon the side next the glass; so that the ideal would require the geometric mean of the two reflections to be equal to that of the two transmissions. A very slight silvering is all that is wanted, such as from its want of coherence and brilliancy would be useless for other purposes; and the bands appear tolerably black, even though the interfering lights are of decidedly unequal intensities. There is, of course, a reflection from the unsilvered surface of the plate. Owing to a want of parallelism in my apparatus, this image was distinctly separated from the other. The two back reflectors were of flat glass, silvered by the milk-sugar process, and used as specula.

The imperfections of the surfaces disturbed the formation of the bands from full accordance with theory. The definition was usually better when the pencils were limited, as by the screens employed to define the incident ray, than when all obstruction was removed. The final adjustments for the distinctness and desired width of bands were made with the eye at the telescope by shifting the reflecting prism, and occasionally by slight displacements of one of the other reflectors.

The tubes enclosing parts of *cd*, *fe*, and containing the electrolyte (diluted sulphuric acid of nearly maximum conductivity), were closed at the ends by plates of parallel glass. The current entered by lateral attachments, so arranged that liquid (or gas) rising or falling from the platinum electrodes would not at first enter the operative part of the tubes. The diameter of the tubes was about $\frac{3}{4}$ inch, and the effective length about 11 inches.

It will be sufficient to give the details of one experiment. The two tubes were connected in multiple arc, and of course in such a manner that the current travelled in opposite directions. The magnitude of the whole current (say, from eight Grove cells) was 1.5 ampère; so that the current *density*, in ampères per sq. cm., was

$$\frac{.75}{\pi \times .38^2 \times 2.54^2} = .26.$$

Now, one of the interfering rays travelled 22 inches, or 56 centimetres, with the current, and the other ray the same distance against the current. On *reversal* of the current no shift of the bands could be perceived, under conditions where a shift of $\frac{1}{10}$ of a band must have been evident. Hence we may conclude that a current of the above-mentioned density does not accelerate (or retard) the propagation of light in the ratio of $\frac{1}{10} \lambda$ to 224 cms. In the liquid we may take $\lambda = 4 \times 10^{-5}$ cm.; and if we reduce the result so as to correspond to density unity, we may say that in dilute sulphuric acid a current of one ampère per square centimetre does not alter the velocity of light by 1 part in 13 millions, or by 15 metres per second.

It would probably be possible to carry the test ten or fifteen times further by the use of much larger tubes and a more powerful battery, but there seems to be no sufficient encouragement at present to make the attempt. The case would, of course, be very different were anyone to show by *a priori* argument a reason for expecting an effect of this order of magnitude.

Electro-Chemical Thermo-Dynamics. (Letter from Professor WILLARD GIBBS to the Secretary of the Electrolysis Committee of the British Association.)

New Haven: November 21, 1887.

Professor OLIVER J. LODGE,

Dear Sir,—As the letter which I wrote you some time since concerning the *rendement* of a perfect or reversible galvanic cell seems to have occasioned some discussion, I should like to express my views a little more fully.

It is easy to put the matter in the canonical form of a Carnot's cycle. Let a unit of electricity pass through the cell producing certain changes. We may sup-

¹ Probably I might say $\frac{1}{20}$, but it is best to be upon the safe side. When the contact was maintained a slight shift was observed, but in a direction independent of that of the current.

pose the cell brought back to its original condition by some reversible chemical process, involving a certain expenditure (positive or negative) of work and heat, but involving no electrical current nor any permanent changes in other bodies except the supply of this work and heat.

Now the first law of thermo-dynamics requires that the algebraic sum of all the work and heat (measured in 'equivalent' units) supplied by external bodies during the passage of the electricity through the cell, and the subsequent processes by which the cell is restored to its original condition, shall be zero.

And the second law requires that the algebraic sum of all the heat received from external bodies, divided, each portion thereof, by the absolute temperature at which it is received, shall be zero.

Let us write W for the work and Q for the heat supplied by external bodies during the passage of the electricity, and $[W]$, $[Q]$ for the work and heat supplied in the subsequent processes.

$$\text{Then} \quad W + Q + [W] + [Q] = 0, \quad . \quad . \quad . \quad . \quad (1)$$

$$\text{and} \quad \frac{Q}{t'} + \int \frac{d[Q]}{t} = 0, \quad . \quad . \quad . \quad . \quad (2)$$

where t under the integral sign denotes the temperature at which the element of heat $d[Q]$ is supplied, and t' the temperature of the cell, which we may suppose constant.

Now the work W includes that required to carry a unit of electricity from the cathode having the potential V'' to the anode having the potential V' . (These potentials are to be measured in masses of the same kind of metal attached to the electrodes.) When there is any change of volume, a part of the work will be done by the atmosphere or other body enclosing the cell. Let this part be denoted by W_p . In some cases it may be necessary to add a term relating to gravity, but as such considerations are somewhat foreign to the essential nature of the problem which we are considering, we may set such cases aside. We have then

$$W = V' - V'' + W_p \quad . \quad . \quad . \quad . \quad (3)$$

Combining these equations we obtain

$$V'' - V' = W_p + [W] + [Q] - t' \int \frac{d[Q]}{t} \quad . \quad . \quad . \quad . \quad (4)$$

It will be observed that this equation gives the electromotive force in terms of quantities which may be determined *without setting up the cell*.

Now $[W] + [Q]$ represents the increase of the intrinsic energy of the substances in the cell during the processes to which the brackets relate, and $\int \frac{d[Q]}{t}$ represents their increase of entropy during the same processes. The same expressions, therefore, with the contrary signs, will represent the increase of energy and entropy in the cell during the passage of the current. We may therefore write

$$V'' - V' = -\Delta\epsilon + t' \Delta\eta + W_p \quad . \quad . \quad . \quad . \quad (5)$$

where $\Delta\epsilon$ and $\Delta\eta$ denote respectively the increase of energy and entropy in the cell during the passage of a unit of electricity. This equation is identical in meaning, and nearly so in form, with equation (694) of the paper cited in my former letter, except that the latter contains the term relating to gravity. See 'Trans. Connect. Acad.' III. (1878), p. 509. The matter is thus reduced to a question of energy and entropy. Thus, if we knew the energy and entropy of oxygen and hydrogen at the temperature and pressure at which they are disengaged in an electrolytic cell, and also the energy and entropy of the acidulated water from which they are set free (the latter, in strictness, as functions of the degree of concentration of the acid), we could at once determine the electromotive force for a reversible cell. This would be a limit below which the electromotive force required in an actual cell used electrolytically could not fall, and above which the electromotive force of any such cell used to produce a current (as in a Grove's gas battery) could not reach.

Returning to equation (4), we may observe that if t under the integral sign has a constant value, say t'' , the equation will reduce to

$$V'' - V' = \frac{t'' - t'}{t''} [Q] + [W] + W_P \quad (6)$$

Such would be the case if we should suppose that at the temperature t'' the chemical processes to which the brackets relate take place reversibly with evolution or absorption of heat, and that the heat required to bring the substances from the temperature of the cell to the temperature t'' , and that obtained in bringing them back again to the temperature of the cell, may be neglected as counterbalancing each other. This is the point of view of my former letter. I do not know that it is necessary to discuss the question whether any such case has a real existence. It appears to me that in supposing such a case we do not exceed the liberty usually allowed in theoretical discussions. But if this should appear doubtful, I would observe that the equation (6) must hold in all cases if we give a slightly different definition to t'' , viz., if t'' be defined as a temperature determined so that

$$\frac{[Q]}{t''} = \int \frac{d[Q]}{t} \quad (7)$$

The temperature t'' , thus defined, will have an important physical meaning. For by means of perfect thermo-dynamic engines we may change a supply of heat $[Q]$ at the constant temperature t'' into a supply distributed among the various temperatures represented by t in the manner implied in the integral, or *vice versa*. We may therefore, while vastly complicating the experimental operations involved, obtain a theoretical result which may be very simply stated and discussed. For we now see that after the passage of the current we may (theoretically) by reversible processes bring back the cell to its original state simply by the expenditure of the heat $[Q]$ supplied at the temperature t'' , with perhaps a certain amount of work represented by $[W]$, and that the electromotive force of the cell is determined by these quantities in the manner indicated by equation (6), which may sometimes be further simplified by the vanishing of $[W]$ and W_P .

If the current causes a separation of radicles, which are afterwards united with evolution of heat, $[Q]$ being in this case negative, t'' represents the highest temperature at which this heat can be obtained. I do not mean the highest at which any part of the heat can be obtained—that would be quite indefinite—but the highest at which the whole can be obtained. I should add that if the effect of the union of the radicles is obtained partly in work— $[W]$, and partly in heat— $[Q]$, we may vary the proportion of work and heat; and t'' will then vary directly as $[Q]$. But if the effect is obtained entirely in heat, t'' will have a perfectly definite value.

It is easy to show that these results are in complete accordance with Helmholtz's differential equation. We have only to differentiate the value which we have found for the electromotive force. For this purpose equation (5) is most suitable. It will be convenient to write E for the electromotive force $V' - V''$, and for the differences $\Delta\epsilon$, $\Delta\eta$ to write the fuller forms $\epsilon'' - \epsilon'$, $\eta'' - \eta'$, where the single and double accents distinguish the values before and after the passage of the current. We may also set $p(v'' - v')$ for W_P , where p is the pressure (supposed uniform) to which the cell is subjected, and $v'' - v'$ is the increase of volume due to the passage of the current. If we also omit the accent on the t , which is no longer required, the equation will read

$$E = \epsilon'' - \epsilon' - t(\eta'' - \eta') + p(v'' - v') \quad (8)$$

If we suppose the temperature to vary, the pressure remaining constant, we have

$$dE = d\epsilon'' - d\epsilon' - t d\eta'' + t d\eta' - (\eta'' - \eta') dt + p dv'' - p dv' \quad (9)$$

Now, the increase of energy $d\epsilon'$ is equal to the heat required to increase the temperature of the cell by dt diminished by the work done by the cell in expanding. Since $d\eta'$ is the heat imparted divided by the temperature, the heat imparted is $t d\eta'$, and the work is obviously $p dv'$. Hence

$$d\epsilon' = t d\eta' - p dv',$$

and in like manner

$$d\epsilon'' = t d\eta'' - p dv''.$$

If we substitute these values, the equation becomes

$$dE = (\eta' - \eta'') dt \quad . \quad . \quad . \quad . \quad . \quad (10)$$

We have already seen that $\eta' - \eta''$ represents the integral $\int \frac{d[Q]}{t}$ of equations (2) and (4), which by equation (2) is equal to the reversible heat evolved, $-Q$, divided by the temperature of the cell, which we now call t . Substitution of this value gives

$$\frac{dE}{dt} = -\frac{Q}{t}, \quad . \quad . \quad . \quad . \quad . \quad (11)$$

which is Helmholtz's equation.

These results of the second law of thermo-dynamics are of course not to be applied to any real cells, except so far as they approach the condition of reversible action. They give, however, in many cases limits on one side of which the actual values must lie. Thus, if we set $<$ for $=$ in equations (2), (4), (5), (6), and $>$ for $=$ in (8), the formula will there hold true without the limitation of reversibility. But we cannot get anything by differentiating an inequality, and it does not appear *a priori* which side of (10) is the greater when the condition of reversibility is not satisfied. The term $\frac{Q}{t}$ in (11) is certainly not greater than $\eta'' - \eta'$, for which it was substituted. But this does not determine which side of (11) is the greater in case of irreversibility. It is the same with Helmholtz's method of proof, which is quite different from that here given, but indicates nothing except so far as the condition of reversibility is fulfilled. (See 'Sitzungsberichte, Berl. Acad.,' 1882, pp. 24, 25.)

I fear that it is a poor requital for the kind wish which you expressed at Manchester, that I were present to explain and support my position, for me to impose so long a letter upon you. Trusting, however, in your forbearance, I remain yours faithfully,

J. WILLARD GIBBS.

Authorship of Electrolytic Theory. (Translation of a Letter from Professor CLAUSIUS, received by the Secretary of the Electrolysis Committee of the British Association.)

Bonn : October 2, 1887.

Dear Sir,—While I render you my best thanks for kindly sending me the Report of the E.C.B.A., which I have read with much interest, I should like to be allowed to make a remark on one point arising in it. You mention the theory of electrolytic conduction, started by me in the year 1857, by the name, 'the old Williamson-Clausius hypothesis;' and in similar terms my theory is referred to in other parts of the circular you have been good enough to send me.

This nomenclature must arouse in the minds of readers not fully conversant with the literature of the subject a question as to whether Williamson has not also devised a theory to explain electrolytic conduction.

This, however, is not the case. Williamson was only considering a purely chemical process—namely, the formation of ether, and his theory relating to this was contributed to the British Association in Edinburgh. On electrolytic conduction he had not spoken a single word. I am quite convinced that he himself has not the least intention of claiming the merit of having started an hypothesis for the explanation of electrolytic conduction.

By other authors the theory of electrolytic conduction is continually referred to as mine. Of English authors I will only mention Maxwell, who, in his

'Treatise on Electricity and Magnetism,' Vol. I., p. 309, speaks of 'the theory of Clausius' simply.

I trust, therefore, that you will kindly arrange so that terms conveying a meaning not intended by the Committee may be avoided by them, lest they excite a false impression in the minds of readers.—With assurances, &c., faithfully yours,

R. CLAUDIUS.

On the Conduction of Alloys and Solid Sulphides.

By J. H. GLADSTONE, Ph.D., F.R.S., and WALTER HIBBERT, F.I.C.

The following experiments were instituted in connection with the work of the British Association Committee on Electrolysis. One of the questions originally raised was whether there was any resemblance between the conduction of an alloy and that of an electrolyte; or, to put it in another way, whether the passage of an electric current through an alloy is associated with any separation of its constituents.

The method adopted by us depends on the assumption that any such separation would produce changes of resistance, the changes being, in all probability, different at one electrode from what they would be at the other.

The apparatus consisted of a U tube of glass of the following dimensions:—

Internal diameter, 0.45 centimetres; total length, 28 centimetres; horizontal portion, 11 centimetres; each vertical portion, 8.5 centimetres. The ends of the tube were carefully fitted with corks, so bored as to form large terminal cups, as shown in section in the above diagram.

In the middle of the horizontal part of the U a platinum wire was fused through the glass for the purpose of making connection with the central part of the alloy whilst the current was passing through it.

The alloy used was the 'fusible alloy,' sold by Messrs. Hopkin & Williams, containing bismuth, lead, tin, and a little cadmium. It was chosen because of its low fusing-point, which enabled us to keep it perfectly liquid at the temperature of boiling water. A suitable quantity was fused and poured into the U tube, some care being needed to drive out all air-bubbles. The tube was then placed in a water oven and kept at 100° Centigrade. Connections were made through the lid of the oven by means of three thick insulated copper wires, two of them going to the cups at the end of the U tube, and the third to a mercury cup at the bottom of the oven, into which there dipped the platinum wire from the middle of the U. By means of these connections the two halves of the tube were joined to the ends of a metre bridge wire, and the ratio of the resistance of one half to that of the other obtained in the usual way.

In the earlier experiments a slight modification of Carey Foster's arrangement of the bridge was tried, but it was found a little inconvenient for these particular experiments, and was therefore replaced by the ordinary simpler form.

The currents employed varied in different experiments from 5 down to 0.2 amperes, running generally for four or five hours, with two or three tests during that time. On one occasion a current of about 0.4 ampère was continued for twenty-four hours.

The results of the experiments were always negative, no change of resistance being detected which did not fall within the limit of probable error.

It ought to be pointed out that the sources of error were considerably greater than usual. The resistances under comparison were so small, and such great temperature differences existed between the various junctions, that great pre-

cautions had to be taken against thermo-electric disturbance. Errors arising from this source were generally eliminated by repeating the observations with a reversed current. In some cases the battery circuit was completed after the index of the galvanometer had come to rest under the action of the thermo-current; but this was not considered so decisive as the other method.

A few experiments were made by a method depending on the fall of potential in one half of the tube compared with that in the other half, but they yielded the same negative result.

This conclusion is true for nearly all our experiments to 1 part in 500 and for many of them to 1 part in 1,000. The conclusion is strengthened by the fact that when small changes did occur they were shown to be due to some influence not dependent on the direction of the current. Thus in one experiment already alluded to, in which the current continued for twenty-four hours, a change of zero amounting to 0.7 of a millimetre was observed. As this was a fairly large change compared with the usual result, the current was reversed for twelve hours. At the end of that time the zero had moved a little further in the *same* direction, showing that the alteration was due to some other cause than the one we were seeking to detect.

One or two data obtained incidentally may be of interest.

The alloy had a specific resistance at 100° C. of about 107,000 c.g.s. units—i.e., a cubic centimetre of it had between opposite faces a resistance of .000107 ohm.

To assure ourselves that changes in composition would affect the resistance two experiments were made. To the alloy in one half of the U tube 0.5 per cent. of lead was added. This was done with some care, but it could hardly be expected that the distribution of the lead would be uniform through the one half and confined to it. However, a fall in the ratio of the resistances of the two limbs of nearly 3 per cent. was noticed. In the second experiment the amount of lead added was 1 per cent., and the fall in resistance of that half of the tube was about 5 per cent.

This negative result is in accordance with that arrived at by Professor Roberts-Austen with other alloys and by a different method.

SOLID SULPHIDES.—It is well known that certain mineral sulphides conduct electricity, and it is evident that if such a compound were placed between two sheets of silver, and an electric current passed through, the condition of the silver would at once reveal whether any sulphur had combined with it on the one side, or any metal had been deposited on the other. Experiments made some years ago gave a negative result, but they have been repeated more carefully recently. The plates of silver were connected with an astatic galvanometer and a battery, and the current varied in different experiments from a very small value up to about 1.5 ampère.

The condition of the sulphide was also varied. Sometimes we used small blocks of native galena, cinnabar, &c., ground smooth on two opposite faces; in other experiments we employed finely divided powders.

The sulphides generally produced a slight tarnishing of the plates, but it was found that something similar occurred without the current. In the case of three sulphides—lead, mercury, and copper—however, the tarnishing was extremely small compared with what would have occurred if the whole current had passed electrolytically. We concluded, therefore, that there was no electrolytic conduction, or, if any, very little in comparison with the non-electrolytic.

During the course of these experiments it came to our knowledge that Hittorf, in 1851, had experimented on silver sulphide fused into solid cylinders, and showed that the sulphide is electrolysed with the formation of threads of metallic silver. This we confirmed, working with tightly compressed powder; and we observed that the current was at first small, but rose gradually, and then jumped to a much greater value, no doubt at the moment when the space between the poles was bridged over by the metallic threads. Under the microscope the reduced silver seemed to be fused. Hittorf observed a similar decomposition of cuprous sulphide.

The following are the additional results we have arrived at:—

Lead Sulphide.—This compound, whether in the form of powdered galena or the precipitated sulphide, conducts pretty easily. It always gave a slight indication of

polarisation after the current had passed through, but so slight that it might have been due to impurity. The conduction was almost entirely non-electrolytic.

Copper Sulphide, CuS.—This compound also, whether fused and powdered or obtained as a precipitate, conducts readily enough. When silver electrodes were used no polarisation could be detected. With platinum electrodes very little. The silver plates remained bright when the fused sulphide was employed; with the precipitated substance they were both marked.

Iron Sulphide.—Natural iron pyrites gave no polarisation or discolouration of the silver electrodes. An artificially-prepared fused compound gave a little polarisation, but its composition varies.

Bismuth Sulphide.—Conducts very little. No polarisation was obtained.

Mercury Sulphide (cinnabar).—Same results.

Potassium Sulphhydrate.—Dried at a red heat, this was found to be a non-conductor. The same appears to be true of the *sulphides of calcium and barium*.

It appeared, therefore, that solid sulphides divide themselves into two classes: those which are electrolysed, and those which conduct with little or no decomposition. Now it happens that the two sulphides which are easily electrolysed—namely, the silver and cuprous sulphides, are of analogous constitution, Ag_2S and Cu_2S , and differ in that respect from the others. It occurred to us that the thallium sulphide Tl_2S might be like them. Mr. Crookes kindly gave us some small bars of this compound, saying at the same time that he had found its power of conducting electricity to be very rapidly augmented on heating. We found that it rapidly increased in conductivity to about 105° , about which temperature it also softened, and the conduction was accompanied by considerable electrolysis. We dissolved up this specimen and estimated the thallium and sulphur. The results showed that it contained much more sulphur than the compound Tl_2S . It was probably a mixture of that body with the compound Tl_2S_3 , which is said to be soft even at a summer temperature.

We therefore prepared a specimen of the thallious sulphide Tl_2S ourselves, and, after carefully drying it at 125° in a current of carbonic acid, found it on analysis to be nearly pure Tl_2S . This compound was not melted even at a temperature of 290° – 300° C. It shows a small conduction at ordinary temperatures, and up to 100° , after which it increases slowly to about 170° . Beyond this the increase is more rapid.

Throughout the greater part of this range of temperature—that is, from 50° upwards—there was evidence of polarisation, the value of which increased very rapidly as the temperature rose from 100° to 130° . Measurements were made by the potentiometer method, the highest value obtained being very nearly 0.3 volt.

The results, therefore, in this case agree with our anticipation that solid sulphides similar in constitution to the silver and cuprous sulphides are capable of being electrolysed; while solid sulphides of the type MS conduct with little or no decomposition.

On the Electrolysis of Thallium Trisulphide.

By J. H. GLADSTONE, Ph.D., F.R.S., and W. HIBBERT, F.I.C.

In a communication made to the Committee in the early part of this year we gave the results of some experiments on the electrolysis of solid sulphides. It was pointed out that the sulphides electrolysed up to that time—silver and cuprous sulphides—were of analogous constitution, containing two atoms of metal to one of sulphur. Led by this circumstance, we succeeded in getting electrolysis of another similar compound—thallious sulphide, Tl_2S .

Some of our early experiments happened to be made with a compound containing more sulphur than that required by the formula Tl_2S , and this suggested an attempt to electrolyse the compound of thallium and sulphur which has the formula Tl_2S_3 . This compound is soft and plastic at the temperature of a warm summer day, and might reasonably be expected to show electrolysis.

We found some difficulty in preparing the compound by the method given—i.e., by fusing thallium with excess of sulphur, and driving off the excess at a very high

temperature. It was much easier to obtain it by first making some pure Tl_2S and then gently heating this with the theoretical amount of finely-divided sulphur. At about the melting-point of sulphur ($120^\circ C.$) combination ensues, and at a slightly higher temperature appears complete. Thus prepared, Tl_2S_3 is a dark grey compound, behaving like an extremely viscous body. Under comparatively slight pressure, and at ordinary summer temperatures, it can be easily bent and moulded.

In testing whether this compound could be electrolysed, we enclosed a little of it in a glass tube and then pressed a metallic electrode into contact with it at each end. Sometimes these electrodes were made of silver, but in most of the experiments they were of platinum.

Three Grove's cells were employed. The resistance of the trisulphide was very high, and the deflection, even when using a high-resistance Thomson reflecting galvanometer, was generally small. At $12^\circ C.$ the current was very weak, but it showed a tendency to increase if the battery was left on for an hour or two. The polarisation was not detectable with such a small current. At temperatures ranging from 20° to 40° or $50^\circ C.$ the current increases, and polarisation becomes evident. The values obtained for the polarisation E.M.F. vary so much with the temperature and the duration of the electrolysing current that only an approximation can be stated. Generally speaking, the polarisation E.M.F. increased with the electrolysing current, and reached in some cases a value somewhat over half a volt. In one case a potentiometer measurement indicated approximately 0.8 volt.

It was observed, after all the experiments, that the pellet of trisulphide was no longer plastic, but had become hard and brittle. As this might be indicative of a change in composition, a little of the sulphide, simply enclosed in a glass tube, was sometimes placed in the water-oven along with the specimen undergoing electrolysis. At the close the two specimens presented about the same degree of hardness and brittleness; and we therefore concluded that the trisulphide is subject to a molecular change through heat, independent of any effect due to electrolysis.

The effect of the molecular change was evident during the experiments. After an hour or so of heating the current would begin to diminish and fall towards zero. The diminution was probably caused by an increase in the resistance of the trisulphide, seeing that the polarisation E.M.F. was little altered so long as it could be measured. It was this phenomenon that generally brought the experiments to a close.

We thought this increased resistance might be due to a decomposition of the compound Tl_2S_3 at the temperature employed (30° – 50°), accompanied by a separation of sulphur. On trying, however, to obtain evidence of such separation, by treating the specimens with carbon bisulphide, we quite failed. Only a trace of sulphur was separated, and the quantity was practically the same from both the original and the changed specimens.

The alteration in properties, which we have supposed to be due to a molecular change, has a considerable bearing on the interpretation of the results; for in its plastic form the trisulphide can hardly be looked upon as a solid comparable with the cuprous, argentic, and thallious sulphides. In the hard and brittle form it can hardly be classed as a conductor. Thus our previous conclusion is not invalidated by it.

On the Polarisation of small Electrodes in Dilute Sulphuric Acid.
By Dr. FRANZ RICHARZ, of Berlin.

I examined the greatest value the electro-motive force of galvanic polarisation possesses with platinum wires of very small surface in the electrolysis of dilute sulphuric acid.

I. Older experiments by Buff (Pogg. 'Ann.' 130, p. 341, 1867) and Fromme (Wied. 'Ann.' 33, p. 80, 1888) have given under those conditions 3.3 and 4.3 Daniells for the maximum. In these experiments the polarisation is calculated from measurements of the intensity of the galvanic current during the electrolysis, tacitly assuming that the resistance of the decomposition cell is independent of the intensity of the galvanic current. The correctness of this supposition has not

been proved. I tried experiments by similar methods, and obtained yet greater values of the polarisation; it was calculated with a current density of 12 ampères per square centimetre as 4.4 Daniells, and increased more and more with increasing intensity of the galvanic current. It is very improbable that this can be right. By supposing, however, that the resistance of the decomposition-cell is not independent of the intensity, but decreases in a fixed manner with increasing intensity, the calculation of the same experiments gives small and constant values of polarisation.

II. Such a decrease of the resistance of a decomposition-cell with very thin platinum wires with increasing intensity may be inferred from the following reasons:—

(a) The resistance of the cell has its principal seat in the fluid layers immediately near the electrodes. These layers, however, grow warmer the greater the intensity is, and the warmer these layers are, the less their resistance will be. The heating so produced can be very great. Calculation shows for my experiments that (loss of heat not being taken into account), at the greatest intensities employed (*circa* 1 ampère), the fluid immediately at the electrode is heated to boiling heat after a seventh of a second. The heating is proved experimentally by the appearance of a phenomenon very similar to Leidenfrost's phenomenon, and depending on the formation of a steam-case round the electrode.

(b) With small intensities the evolution of gas does not take place over the whole wire but only on some spots of it; with the least intensities only on one spot.

(c) The diffusion in the fluid of the gases evolved by electrolysis corresponds to a 'transition-resistance' (H. von Helmholtz, 'Sitzungsber. d. Berl. Akad.' 1883, p. 664). That resistance must relatively be the more important as compared with the other effects in the cell, the smaller the latter are; therefore it must appear as a resistance increasing with decreasing intensity.

These three causes produce a considerable decrease of the resistance with increasing intensity. The hypothesis according to which the methods mentioned under I. gave such very high values for the polarisation is thus not fulfilled.

III. I have made measurements of the polarisation of very thin platinum wires in sulphuric acid, by a new method, which is independent of the resistance of the decomposition-cell. The circuit of the galvanic current, which contains the polarising battery B and the cell *z*, is closed by the first contact *c*₁ of Helmholtz's pendulum-interrupter (Wied. 'Electr.' iv. p. 219, 227). A branch wire proceeds from either side of *c*₁ to a galvanometer *g*. This branch circuit includes the second contact *c*₂ of the pendulum-interrupter, and a very great resistance (40,000 Siemens units). While *c*₁ is closed the current is very weak in the galvanometer. In the short time between the interruption of *c*₁ and *c*₂ a current, strong for the sensibility of

the galvanometer, goes through it. The impact of the galvanic current is proportional to the electromotive force of the battery minus the polarisation. From the deflection of the galvanometer I can calculate the mean value of the polarisation in the time between the interruptions of *c*₁ and *c*₂, and by diminishing this time more and more I can judge if the polarisation during this time has already decreased considerably. I shortened that time to 0.00059 second, and diminished the surface of the platina wires to 0.8 sq. mm., and increased the intensity at those electrodes to 0.4 ampère. The values of polarisation which I found were never greater than nearly 2.4 Daniells, and, taking account of the decrease of polarisation, its value before

the interruption would amount to at most 2.5 Daniells. That is, the same maximum as was found for the polarisation also with large platinum plates in dilute sulphuric acid. Now, with thin wires a great deal of ozone, peroxide of hydrogen, and persulphuric acid is evolved at the anode; at plates only common oxygen. As the electromotive force of polarisation has the same value in either case, it is to be concluded from the facts that the evolving of those hyper-oxides has no influence upon the polarisation; and, further, that the primary electrolytical process by which the strength of the polarisation is chiefly conditioned is the very same during the development of common oxygen as at the evolving of O_3 , H_2O_2 and $S_2O_8H_2$ from dilute sulphuric acid.

IV. The influence of the formation of $S_2O_8H_2$ on the polarisation may be judged, too, from the electromotive behaviour of platinum in $S_2O_8H_2$. I found the electromotive force

From which may be calculated

In this last cell the process effected by the galvanic current is the reduction of the persulphuric acid, according to the formula

Its heat of formation (Berthelot, 'Compt. Rend.' 90, p. 331, 1880) is equivalent to 0.56 Daniell. It is to be concluded from the conformity of the found with the calculated value that the reduction of the persulphuric acid in that cell is a primary electrolytic process. Besides, it must seem very probable that the formation of $S_2O_8H_2$ at the anode, also corresponding to the inverse process, is a primary electrolytic process. To its chemical heat of formation a polarisation of the anode of 0.56 Dan. would correspond. Generally, however, neither the polarisation alone is given by the chemical heat, nor is $S_2O_8H_2$ alone formed under any circumstances at the anode.

Reply to Professor Armstrong's Criticisms regarding the Dissociation Theory of Electrolysis. By SVANTE ARRHENIUS.

In his communication at Manchester to the Electrolysis Committee of the British Association, Professor Armstrong has honoured my views on electrolysis with a critical analysis from a chemist's point of view. In the following lines I will attempt to show how the chief objections that he has made can be removed, and also that his views present difficulties which greatly militate against their acceptance.

1 and 2.¹ Professor Armstrong finds it difficult to explain why some single bodies, *e.g.*, silver iodide, conduct electrolytically, whereas other pure bodies, *e.g.*, water or hydrogen chloride, are non-conductors. We certainly are bound to assume that fused silver iodide is to a sensible degree dissociated into its ions, and that the dissociated parts of the non-conductor escape our observation. But it may be remarked that no exact comparison can be made between the two cases, silver iodide being examined at temperatures above 530° (the melting-point of AgI), H_2O and HCl at ordinary temperatures, it being very probable that dissociation increases rapidly with the temperature. Also, too much stress must not be laid on the behaviour of pure bodies or of concentrated solutions, as experience shows that dilute solutions are characterised by very remarkable regularities, analogous to those which obtain in the case of gases, and that these regularities vanish as the solutions attain a greater degree of concentration; indeed, there seems to be no connection between the facility with which compounds are electrolytically dissociated in dilute solutions and the stability of the same compounds in the pure

¹ The numbers correspond with same numbers in Professor Armstrong's paper above referred to, 'Comparison between the Views of Dr. Arrhenius and Professor Armstrong on Electrolysis.' See 1887 Report, p. 354.

state, as Faraday has already remarked. Because of the regularities which characterise dilute solutions, the dissociation hypothesis has reference almost exclusively to matter in this state, and has, in my opinion, very successfully explained a great many of its properties.

3. Professor Armstrong asserts that solutions in absolute alcohol oppose a practically infinite resistance. This view is not supported by the recent investigations of Fitzpatrick and Hartwig, from which it seems to follow that 'any neutral solvent renders electrolysis possible,' in accordance with the demands of the dissociation electrolytic hypothesis.

4. According to Professor Armstrong, on the dissociation hypothesis, both water and salt are to be regarded as dissociated; nevertheless, the dissociation hypothesis assumes that conduction takes place only through the agency of the atoms of the dissociated salt, and not at all through that of the water. From chemical facts, *e.g.*, the partial decomposition of certain salts into base and acid by large quantities of water, it is very probable that water is to a very slight degree dissociated into H and OH.¹ But experiments show also that this occurs to an extent so extremely small that it will perhaps for ever be impossible to detect it by measuring the conductivity of water. Also, I have essayed to show that the only fact cited in favour of a sensible conductivity of water can be satisfactorily explained without this assumption. In the same manner, different electrolytes, *e.g.*, HCl and $\text{C}_2\text{H}_3\text{O}_2\text{H}$, are very differently electrolytically dissociated by the same quantity of water, so that the one conducts very well, the other hardly sensibly; but we know representatives of all intermediate stages between these two extremes, so that there is no ground for assuming anything but a quantitative difference. Experiments on the conductivity of pure water, or of dilute salt solutions, lead to the assumption that water is not dissociated to any perceptible degree. If, therefore, as Professor Armstrong asserts, the opinion is common among chemists that in the case of the electrolysis of ammoniacal solutions water is (sensibly) electrolysed, then is this opinion a remnant of old views now abandoned through force of incontestable arguments?

6. In his article Professor Armstrong makes no objection to the dissociation electrolytic hypothesis, but says: 'I do not mean for one moment to assert that anything which we know of the conditions on which chemical change depends negatives beyond question the dissociation hypothesis.'

7. Professor Armstrong interprets the figures of Lenz concerning the parallelism between diffusivity and conductivity of alcoholic aqueous solutions as an 'almost conclusive argument in favour of his theory.' It must be remarked that there are many exceptions to this rule. Thus, *e.g.*, MgSO_4 and cane sugar diffuse nearly at the same rate (Graham), although in aqueous solutions MgSO_4 is a good conductor, while cane sugar seems not to conduct at all; consequently, the two phenomena are not of the same order, as they should be according to Professor Armstrong's hypothesis. 'The diminution in conductivity and also in diffusivity as the amount of alcohol is increased is most striking. If the solvent be neutral, the substitution of alcohol for water should have little influence; but if, as I suppose, the solvent be active, alcohol being far less active than water, the effect to be expected is precisely of the nature of that observed.' In coming to this conclusion a very important thing is lost sight of. The conductivity depends on two circumstances—viz., the degree of electrolytic dissociation, and the friction which the ions must overcome in their passage through the solution. The first circumstance must, as Professor Armstrong asserts, have but little altered in Lenz's experiments with diluted KI and NaI; the diminution in conductivity must consequently have chiefly depended on the increase of the friction with the quantity of alcohol, which is *a priori* very probable. Evidently one must expect that the diffusivity also diminishes as the internal friction increases, and in this manner the parallelism between conductivity and diffusivity in Lenz's figures is quite explicable by means of the electrolytic dissociation hypothesis.

8. 'Why, then, should it (the electromotive force) not give direction to the moving molecules, if these are still possessed of "residual affinity"—i.e., if some

¹ Wied. *Annalen*, xxxiii., p. 58, and *Phil. Mag.* (5), xxiv., p. 377.

portion of the original charge of the atom be still unneutralised?' According to this passage I cannot understand Professor Armstrong to mean otherwise than that the molecules will be directed by the electromotive forces, and consequently themselves move along the lines of flow. This way of viewing the question would lead one to expect the molecules to separate at the electrodes; but it is found experimentally that not molecules but ions are transported to the electrodes.

9. Professor Armstrong finds it difficult to explain why phenylpropionic acid $C_6H_5.C\equiv C.CO_2H$ conducts better—i.e., is more dissociated, than hydrocinnamic acid, $C_6H_5.CH_2-CH_2.CO_2H$. But there are other peculiarities, which, perhaps, are very nearly connected with this circumstance, viz., the physical properties (heat of combustion, refraction of light), which indicate that the triple union in $C_6H_5.C\equiv C.CO_2H$ is less firm than the simple union in $C_6H_5.CH_2-CH_2.CO_2H$.

10. The formula proposed by Professor Armstrong—

$$C = E/R,$$

'C being the amount of change, E the intensity of the total chemical effect,' and R the resistance of the solution in which the interaction takes place, is not verified by experience. Thus, in the case of the hydrolysis of ethylic acetate by means of bases, 'the intensity of the total chemical effect' (E) must be but very little influenced by the presence of neutral salts; R, on the contrary, very much. But experience shows that 'the amount of change' (the velocity of interaction C) alters but very little (for strong bases) if R be increased by addition of neutral salt from 1 to about 20. In the case of ammonia C decreases extremely rapidly, when R decreases in consequence of added neutral salt. These phenomena are easily explained by the electrolytic dissociation hypothesis, the velocity of interaction being proportional to the quantity of OH in the form of ion.

The arguments brought forward by Mr. Crompton on the conductivity of sulphuric acid seem to me not very convincing in favour of the view that hydration of H_2SO_4 should condition the electrolytic conductivity.¹ There is no reason mentioned why the second derivative d^2k/dp^2 (where k is conductivity and p concentration of the acid in per cents.) should have angular points at the places mentioned; on the contrary, the author says that he had expected to find such angular points in the dk/dp curve, but when he did not find them there he proceeded to the examination of d^2k/dp^2 . The author does not take heed of the errors of experiment; a search would probably have shown that these errors in many cases are of the same magnitude as d^2k/dp^2 itself.² Further, the author does not find the same hydrates as Mendeleeff ($H_2SO_4 + 24 H_2O$ not appearing in Mendeleeff's curve, $H_2SO_4 + 6H_2O$ not being marked by Crompton's curve). The part of Crompton's curve between H_2SO_4 and $H_2SO_4 + 2H_2O$ can hardly be considered as consisting of two straight lines, as the author asserts. The artificial nature of the proposed formulæ is manifested by the circumstance that they give very different values of k at the limiting points where two formulæ should be applicable. Moreover, there is a very important difference between the views of Mendeleeff and of Crompton. Mendeleeff says, 'Ich habe schon lange die schwachen Lösungen als die interessantesten angesehen und dieselben dem zerstreuten oder verteilten Zustande der Materie in Dampfform an die Seite gestellt. Die bemerkenswerten Untersuchungen von van 't Hoff haben gegenwärtig dafür einen vollständigen Beweis erbracht,' whereas, according to Mr. Crompton, dilute solutions are characterised by their irregularities.

The above observations will, I believe, suffice to show that the objections

¹ In saying this I wish not to deny that some (but very few) hydrates (e.g., $H_2SO_4 + H_2O$, as Kohlrausch has stated) exert an influence on the conductivity, but only to say that the assertions of Mr. Crompton are to a very high degree exaggerated.

² Being fully conscious that existing data are insufficient for the complete discussion of the problem, Mr. Crompton is engaged in determining the change in conductivity with concentration of a number of solutions; and with the object of discriminating between errors of experiment and true changes in direction of the curves he is paying particular attention to the influence of temperature (H. E. A.).

urged against the dissociation electrolytic hypothesis are unsatisfactory, and that the arguments in favour of the residual affinity hypothesis need a more convincing corroboration than hitherto given. On the other hand, the dissociation electrolytic hypothesis has latterly acquired a highly increased probability, as the lowering of the freezing-point on addition of salts to water, and the additive properties of salt solutions can be explained by it. In a preliminary notice Ostwald has announced that the conductivity of acids and bases can be calculated upon the basis of this hypothesis; and in a paper soon to be published in the 'Zeitschrift f. Phys. Ch.' I will attempt to prove that the known facts regarding conductivity of mixtures, velocity of interaction, and double decomposition between electrolytes can easily be accounted for on the same hypothesis.

Note on the foregoing Reply. By HENRY E. ARMSTRONG.

It is not, I think, desirable for me to attempt to reply at length to Dr. Arrhenius; evidently he retains his original position, but apparently he has not appreciated the character of all my arguments. Thus I cannot imagine how he conceives (§ 9) that any conclusion as to the triple union in the acid $C_6H_5.C\equiv C.CO_2H$ being less firm than the simple union in $C_6H_5.CH_2-CH_2.CO_2H$ —which I entirely dispute (*cf.* 'Phil. Mag.' 1887, 23, 103)—affects the question at issue, which is whether phenylpropionic or cinnamic acid is the more readily separable into its ions, *i.e.*, $C_6H_5.C\equiv C.CO_2$ and H in the one case, and $C_6H_5.CH_2.CH_2.CO_2$ and H in the other.

R in the formula $C=E|R$ (§ 10) was never regarded by me as simply the resistance of the *solution* in which the interaction takes place; it is the resistance of the *circuit* in which interaction occurs. This latter may be quite different from the former, as of a number of substances in solution some only may be capable of entering into the true circuit of change. The influence of added neutral salt may be of a very complex character, and until we know more of the constitution of solutions it is very difficult to arrive at any decision as to its exact character.

No doubt I exaggerated; and should have said (§ 3) that the resistance of alcoholic solutions is very great in comparison with that of corresponding aqueous solutions. I cannot accept either Fitzpatrick's or Hartwig's results as final, interesting as they are, as they were obtained with 'commercial' alcohols; it is very important that *pure* alcoholic solutions should be examined, but this would be a task of exceptional difficulty.

Dr. Arrhenius says (§ 7) that diminution in conductivity on addition of alcohol must chiefly depend on the increase of friction with the quantity of alcohol, *which is à priori very probable*. But is it? We know that alcohol does occasionally form compounds corresponding to hydrates, but as a rule they are far less stable than the hydrates. To the chemist it would therefore seem probable, *à priori*, that friction would diminish with the quantity of alcohol. Cane sugar, as Dr. Arrhenius points out, appears not to be a conductor in aqueous solution, nor is water: therefore, neither is appreciably dissociated in aqueous solution, according to the dissociation hypothesis; yet cane sugar may be hydrolysed by mere heating with water alone. This and a multitude of similar facts appear to me to weigh heavily against the dissociation hypothesis.¹

I cannot believe that the sudden increase in conductivity of solid silver iodide (§§ 1, 2) at about 150° is due to a sudden dissociation of the molecules into

¹ The hydrolysis of cane sugar under such circumstances is conceivably conditioned by the presence of metallic salts, derived from the glass vessel in which the operation is performed. A more effective argument is supplied by the extraordinarily rapid hydrolysis of cane sugar, which is induced by the unorganised ferment *invertase*, derivable from yeast. As typical of the mode of action of such a substance, I may refer to the hydrolysis of the isocyanides R.NC of Gautier and Hofmann, which are unaffected by alkalies, but immediately attacked by aqueous acids: it is significant that these cyanides form crystalline compounds with hydrogen chloride and a number of anhydrous acids, and that the compounds at once interact with water.

the constituent atoms or ions; the change appears to me to be precisely of the character of that which occurs when ice suddenly liquefies at 0° , and may equally be regarded as the result of a sudden alteration in molecular structure.

I will only add that I have attempted to take into account the properties of matter in all states, not merely the state of extreme dilution.

The following remarks by the Chemical Secretary, Dr. Armstrong, are appended, in order to direct attention to what he considers the uncertainty in which our conceptions of the fundamental phenomena of electrolysis are still enshrouded, notwithstanding the very definite assertions of recent foreign workers:—

There can be no doubt that the work done during the past year—which in many ways has been one of remarkable activity—has tended more and more to favour the acceptance of the dissociation theory of electrolysis, that the conviction has been strengthened that electrolysis is primarily an affair of atoms: indeed, so far has this idea gained ground, that it is even argued by Arrhenius, whose conclusions are accepted by Ostwald and others, that in dilute solutions of hydrogen chloride, for example, as much as 90 per cent. of the HCl is dissociated into its ions. Prof. J. J. Thomson, in his recent work, 'Applications of Dynamics to Physics and Chemistry,' has, I think, very happily criticised this conclusion in the following passage (p. 213):—

'The reasons given for this conclusion do not seem to me to be very convincing, and the experimental results on which they are based seem to admit of a very different interpretation. The supporters of this theory urge that, for the salt to produce the effect which in some cases it does, it is necessary to suppose that the molecules of the salt exert a greater pressure than they would if they occupied the same volume at the same temperature when in the gaseous condition. This reasoning is founded on the assumption that all the effects due to the dissolved salt may be completely explained merely by supposing the volume occupied by the solvent to be filled with the molecules of the salt in the gaseous condition. Now, though we may admit that the salt does produce the effects that would be produced by this hypothetical distribution of gaseous molecules, still it does not follow that these are the only effects produced by the salt. The salt may change the properties of the solvent, and the effects attributed to the dissociation of the molecules may in reality be due to this change.'

Deville, who studied the behaviour of hydrogen chloride at high temperatures by means of his well-known apparatus with an internal cooled tube, observed only traces of dissociation at 1300° , and Crafts and F. Meier could detect no appreciable dissociation in porcelain vessels at 1500° , although in platinum at about 1700° , according to Victor Meyer and Langer, it is to a considerable extent resolved into the component elements. That a gas of such stability should be almost entirely dissociated by mere dissolution in water is to me incredible.

Apart from actual electrolytic studies such as those of Arrhenius and Ostwald, the most important influence in forming opinion has been exercised (a) by van 't Hoff's masterly generalisation (cf. 'Phil. Mag.,' 1888, 26, 81), to which Prof. J. J. Thomson is referring in the above-quoted passage, that the molecules of dissolved substances in dilute solutions exert the same pressure as they would if they were in the gaseous state at the same temperature and volume; and (b) by the introduction of Raoult's method of ascertaining molecular weights of dissolved substances by determining the extent to which they depress the freezing-point of the solvent (cf. 'Chemical Society's Transactions,' 1888, 610). While recognising the beauty of the conceptions, and while ready to admit that they may be applicable in many cases, my opinion is very much that expressed by Prof. J. J. Thomson. I agree with him that it is both possible and probable that a change in the constitution of the solvent is effected by the dissolved substance (cf. 'Chemical Society's Transactions,' 1888, 125). The extraordinary effect on the properties of gold and copper, for example, of small amounts of certain foreign matters, so well known to

¹ Cf. Ostwald and van 't Hoff's *Zeitschrift für physikalische Chemie*.

electricians in the case of copper, and which has recently been brought prominently into notice in the case of gold by Prof. Roberts-Austen, may be cited in illustration of the kind of effect on the solvent which conceivably may arise.¹

The arguments in favour of the dissociation theory appear indeed to be based on a narrow interpretation of the results: the dissolved substance alone is regarded as active, the solvent is neutral; the indubitable complexity of the phenomena of dissolution and of chemical interchange generally is entirely left out of consideration. Many chemists and physicists continue to regard values as simple constants which there is the strongest reason to believe are composite. The law of the constancy of the so-called atomic heats of the elements is an illustration. It is well known that in the case of the majority of the elements the product of specific heat by atomic weight is approximately a constant: we are thereby enabled in many cases to determine *atomic* weights, but, be it noted, by a measurement effected with the aid of molecules, not of atoms; these molecules are undoubtedly of very varied atomic complexity, and it would seem that we are bound to assume that the nearly constant value of the so-called atomic heat is the outcome of a kind of balance—that as, in raising the temperature of a solid, work is done *inter-* and *intra-*molecularly, the amount of intermolecular work is greater in some cases and less in others, and the amount of intramolecular work proportionally less or greater, the amount per atom being, however, about the same in most cases. May we not interpret the simple results obtained by Raoult's method in a similar manner? Is it not probable that the effects are in reality often produced by molecular complexes of the *fundamental* molecules, the latter corresponding to the atoms to which we refer the result in discussing variation of specific heat with atomic weight? Perhaps it is only in cases in which *atomic* rearrangement has taken place that Raoult's method affords evidence of increased molecular complexity, as in the case of aldehyde and paraldehyde, for example; in such a case as that of dextrose, which, whether freshly dissolved or not, produces an effect such as is required on the assumption that its molecule has a weight corresponding to the formula $C_6H_{12}O_6$, there may be no atomic rearrangement but the mere juxtaposition of molecules involved in the formation of a 'molecular' compound.

Arrhenius, Ostwald and others regard both electrical conductivity and chemical activity as similarly conditioned by the degree of dissociation—in their opinion, very active substances, such as sulphuric acid, are to a large extent dissociated in solution; inert substances, such as acetic acid, are but to a slight extent dissociated in solution. But the adherents of this school all overlook the fact that there are two distinct theories of chemical interchange: the older theory that the interacting molecules initially combine and that the resulting complex then splits up—which may be termed the integration theory; and the more modern dissociation theory. I am led to regard the former as the more comprehensive and generally applicable, especially as comparatively so few compounds are electrolytes, and I venture to think that physicists also would incline more to my belief if they would assume a somewhat different mental attitude towards the facts, and would seek to fully unravel the entire series of changes involved in chemical interactions.

The attention of the Committee has in previous years been directed to the question whether electrolytic conduction and metallic conduction are sharply separated from one another, and last year experiments by Prof. Roberts-Austen were described which appeared to show that alloys do not conduct electrolytically. Prof. J. J. Thomson deals with this question in his already-mentioned work in the following passage (p. 296):—

'There does not seem any necessity for supposing that the passage of electricity through metals and alloys is accomplished in a fundamentally different way from that through gases and electrolytes. For the chief differences between conduction through metals and through electrolytes are—(1) that in electrolytic conduction the components of the electrolyte appear at the electrodes, and we have polarisation;

¹ Prof. Roberts-Austen informs me that the melting-point of gold is lowered to about that of zinc by $\frac{2}{1000}$ of silicon.

and (2) that the conductivities of electrolytes increase while those of metals diminish as the temperature increases.

'A little consideration will show that we could hardly expect to detect [polarisation] in the case of metals or alloys, for here instead of, as in electrolytes, the property of splitting up being confined to a few molecules sparsely scattered through a non-conducting solvent, the whole of the molecules can thus split up; thus the rate of disappearance of any abnormal condition would be almost infinitely greater than in the case of electrolytes, so that if any polarisation were produced it would probably die away before it could be detected. The only case in which we could expect to detect the appearance of the constituents of the conductor at the electrodes is that of the alloys, but even in this case Prof. Roberts-Austen was unable to detect any change in composition in the alloy round the electrodes. We must remember, however, that an alloy differs very materially from an electrolyte, because while in the latter we have a few active molecules embedded in a non-conductor, in the former it is as if the solvent as well as the salt conducted, so that the discharge is not concentrated on a few molecules of definite composition, but can travel by an almost infinite variety of paths.

'Then, again, the statements about the effect of heat on the conductivity of elements and electrolytes though true in general are subject to exceptions; thus, the conductivities of selenium, phosphorus and carbon increase as the temperature increases; that of bismuth is said to increase at certain temperatures; and I have lately found that the conductivity of an amalgam containing about 30 per cent. of zinc and 70 of mercury is greater at 80° than at 15°. We must remember, too, that the rate of increase of conductivity with temperature for electrolytes diminishes as the concentration increases. No sharp line of demarcation can therefore be drawn between the two classes of conductors on this account.

'There does not seem any difference between metallic and electrolytic conduction which could not be attributed to the vastly greater number of molecules taking part in metallic conduction, whilst assuming that in all cases the current consists of a series of intermittent discharges caused by the rearrangement of the constituents of molecular systems.'

I call attention to Prof. J. J. Thomson's remarks both on account of their suggestiveness and in order to point out that we are not in a position to make any such statement as the above regarding selenium, phosphorus and carbon. All observers hitherto have dealt with more or less *impure* substances—everyone, in fact, knows that the so-called carbon which conducts is not carbon at all in the true chemical sense. The conductivity of the substances in question may well be conditioned by the presence of the associated impurities, just as that of water appears to be, and hence their behaviour as electrolytes in respect of temperature changes; Shelford Bidwell's experiments with selenium distinctly favour this view. The differences between metals and non-metals are so great that the chemist has difficulty in resisting the conclusion that there is some very radical distinction to be drawn between metallic and non-metallic matter, although in practice it is impossible to say where metals end and non-metals begin. If it be found that the more nearly pure a non-metal is the greater is the resistance which it opposes, it will some day be possible, perhaps, to classify the elements into metals and non-metals on the basis of their electrical behaviour. In the hope of obtaining evidence on this point I have latterly been engaged in purifying selenium, with the object ultimately of determining its specific resistance; it appears highly desirable that 'metalloids' such as arsenic and antimony should also be carefully examined from this point of view.

The increase in conductivity of bismuth and of Prof. J. J. Thomson's zinc amalgam at higher temperatures may well be due to a change in molecular composition, such as occurs in solid silver iodide, for example; both are cases in which the occurrence of such a change may be considered as probable. That molecular structure is an all-important element in influencing conductivity is all but established by the extraordinary diminution in conductivity effected by minute quantities of foreign elements in the case of copper, for example. In short, I am of opinion that as yet there is no experimental evidence to justify any modification of the time-honoured

conclusion that electrolytic and metallic conduction are essentially distinct phenomena.

Considerable discussion has taken place during previous years in the Committee as to the theoretical determination of E.M.F. on the lines originally indicated by Sir Wm. Thomson from thermochemical data, and attention has been directed to the necessity of taking into account reversible heat effects. I may be allowed to re-iterate the opinion that the evidence tending to throw doubt on Sir Wm. Thomson's law connecting the E.M.F. of a cell with the attendant chemical changes cannot as yet be regarded as in the least degree conclusive, and I venture to offer a brief criticism on the experimental work which has been done in this direction—chiefly by F. Braun (Wiedemann's 'Annalen,' 1882, 16, 561; 17, 593) and by Wright ('Proceedings of the Physical Society'), who have measured the E.M.F.'s of a large number of different cells, and have compared the values found with those calculated from the chemical changes which they *assume* take place in them. The calculated and observed E.M.F.'s were found to agree in only a limited number of cases; in a considerable number the observed E.M.F. fell more or less below that calculated; in a few it was greater; and Wright has specially instanced a number of cells in which the current flows in the opposite direction to that which was to be anticipated.

The measurement of E.M.F. was made either by means of an electrometer; or with a galvanometer, *using currents of very small intensity*; and there is no reason to doubt the results. But both observers were, as I have said, content to *assume* that the chemical changes were of a particular kind, and made no attempt whatsoever to study them in detail from the chemist's point of view.

Now it has been pointed out by Laurie ('Phil. Mag.' August 1886) that the extraordinary results obtained by Wright with aluminium zinc cells, which give an E.M.F. opposed to that calculated from the thermal data (of no less than 1.5 volt in the case of the sulphates), are to be accounted for on the assumption that he was not dealing with aluminium at all but with *aluminium oxide* supported on an aluminium plate. It appears to me, then, that the whole of Braun's and Wright's results are open to this criticism, as the method of measurement which they adopted is one that would permit every surface impurity, every impurity in the

				Chemical Energy in heat units		Observed relative E.M.F.

¹ To reduce heat units per dyad gramme-molecule direct to volts, use the divisor 46,000. The column headed 'relative' in the table would then run, 1.1, .35, 1.18, 2.08, 1.80, 2.16, 1.00, .71, .97.

agents—not excluding dissolved oxygen—to exercise its proper effect. Julius Thomsen has expressly recognised this source of error, and has pointed out the absolute necessity of measuring the E.M.F. of the element in full activity if it be desired to determine the full effect produced by the chemical interchanges which are involved in its action ('Thermoch. Untersuchungen,' III., p. 487). On this account his comparisons of observed and calculated E.M.F.'s may well be set against those of Braun and Wright; they are as given on the preceding page.

When it is borne in mind that in the case of nitric acid the products of change gradually accumulate and produce an effect, the agreement between theory and practice is remarkable.

Braun argues that 'chemical energy' is of the form of heat energy, and that in its conversion into electrical energy in the cell there must therefore necessarily be some loss—some degradation; he terms that fraction of the total energy which takes the form of current the *electromotive efficiency* (Helmholtz's *Freie Energie*), and seeks to connect this with the dissociation temperature of the compounds formed at the electrodes. But if, to use Faraday's words, 'the forces termed chemical affinity and electricity are one and the same,' there is, I imagine, no *a priori* objection to be urged against Sir Wm. Thomson's law.

Braun has based a determination of the 'electromotive efficiency' of a number of chemical changes on the assumption that the E.M.F. developed, for example, between silver, silver bromide, bromine and platinum, is to be regarded as developed simply in the formation from silver and bromine of silver bromide: the value found was 84; that deduced from the heat of formation is 91; so the electromotive efficiency is $\frac{84}{91} = .93$. The experiments were made in a very careful manner, and excep-

tional precautions were taken in purifying and drying the materials, the bromine used being purified by Staas's method. But the fact that a current *was* produced between silver, bromine and platinum, and between silver coated with silver bromide, bromine and platinum is, to my mind, sufficient to throw doubt on the results. It is impossible to prepare *pure* bromine; and it is a fair assumption to make that, if the materials had been pure, no current would have been observed: the determination of the E.M.F. is therefore of uncertain value; the number deduced cannot have been the outcome simply of the formation of silver bromide, as secondary change must have taken place to some extent.

I therefore venture to think that, up to the present, no experimental disproof of Sir Wm. Thomson's generalisation has been given: on the other hand, the fluctuations in E.M.F. which accompany slight changes in composition—such as have been so clearly brought out by Lord Rayleigh's investigation of the Clark cell and by Wright's and Fleming's investigations of the Daniell cell—and also the influence which every change in the conditions exercises on the course of chemical change, would appear to favour the assumption that the electromotive efficiency of chemical change does not differ from the theoretical to the extraordinary extent that Braun suggests.

Before the temperature of dissociation can be taken into account as suggested by Willard Gibbs, we require to know to what extent this depends on the nature of the surface in contact with the dissociating substance.

It is also desirable that a clearer statement of the nature of the reversible heat effects should be given. I can picture to myself that on passing a current across a metallic junction the molecules become somewhat deflected from their original positions, or rotated, and that heat is developed on their subsequent return towards the normal position; but if this be the nature of the Peltier effect, and the converse action occur when thermo-electric currents are developed, it does not appear probable that the reversible heat effects at metal-liquid and liquid-liquid junctions would be of the magnitude to account for the extraordinary differences said to obtain in many cases between observed and calculated E.M.F.

Report of the Committee, consisting of Messrs. W. CARRUTHERS, W. F. R. WELDON, J. G. BAKER, G. M. MURRAY, and W. T. THISELTON-DYER (Secretary), appointed for the purpose of exploring the Flora of the Bahamas.

THE Committee accepted the proposal of the well-known Danish botanist, Baron Eggers, to undertake the work entrusted to them as far as the sum at their disposal would allow. Baron Eggers left Europe in November last and returned in April. Mr. Baker, the principal assistant in the herbarium of the Royal Gardens, Kew, has examined the collection transmitted by Baron Eggers to Kew (a similar one has been sent to the Botanical Department of the Natural History Museum). He has favoured the Committee with the following report upon it:—

The collection made by Baron Eggers contains representatives of 357 numbers. Of these eight are flowerless and indeterminable, and thirty-five represent duplicates or a second form of a species; so that the collection contains 314 species of which the genus can be determined, and these represent 214 genera and 74 natural orders. A catalogue has been made, which will be kept for reference at Kew.

Previous Collections.—A few species were collected in the Bahamas by Catesby early in the eighteenth century, some of which are figured in his 'Natural History of Carolina,' which was published in 1754. In Grisebach's 'Flora of the British West Indian Islands,' the first of the series of colonial floras issued from Kew, which was published in 1864, under 200 species are recorded from the group, mainly on the authority of a collection sent long ago by Mr. Swainson to Sir W. J. Hooker. Between 1877 and 1880 Mr. L. J. K. Brace sent, through Governor Robinson, to Kew seven parcels, containing in all 525 numbers. The collections of Swainson and Brace probably contain about 200 species not gathered by Baron Eggers, so that we now know from the Bahaman group about 500 species.

Analysis of the Bahaman Flora.—Grisebach considered, and no doubt rightly, that the Bahamas, with Turks Island, should be regarded botanically as a distinct province of the West Indian region. In the whole of the British West Indies about 3,000 plants are known. There are about twenty inhabited islands in the Bahaman group, none of which rise to any considerable elevation. Its area is given in the Colonial Office List at 4,466 square miles, which is a little more than that of Jamaica. The islands range over six degrees of latitude (21° to 27° N. lat.), and form the northern province of the West Indian region. It is only here that the Conifers form dense woods at a low level. The Bahaman *Pinus* is endemic, and is not included in Parlatore's monograph. Only the cones were known to Grisebach, but now Brace and Eggers have obtained full material. It has three leaves in a bundle and they are nearly a foot long, so that, as Grisebach suspected, it is allied to *Pinus Tæda*. Baron Eggers describes it as a tree forty feet in height with a trunk a foot in diameter. He has obtained flowerless specimens of the Bahaman cedar, which we did not before possess in the Kew Herbarium. So far as the material goes, it agrees with the Bermudan *Juniperus bermudiana*, which is also found in the mountains of Jamaica. In New Providence this also forms a tree forty feet in height. Several of the more tropical

West Indian orders, *e.g.*, *Dilleniaceæ*, *Piperaceæ*, *Guttiferæ*, *Ternstroмиaceæ*, and *Gesneriaceæ*, are not represented in the Bahamas, and other large characteristically tropical orders, such as *Myrtaceæ*, *Lauraceæ*, and *Melastomaceæ* very feebly. The predominant orders are *Compositæ*, *Leguminosæ*, *Rubiaceæ*, and *Euphorbiaceæ*. There is a very large proportion of genera to species, no genus being represented by more than five or six species. A bamboo was collected without flowers, both by Brace and Eggers. There are three palms, all of which are widely spread West Indian types. Upwards of twenty shrubs, trees, and perennial herbs are supposed to be endemic in the Bahamas. Of these the most interesting are the *Pinus bahamensis* already mentioned; three *Mimoseæ*, *Mimosa bahamensis*, *Acacia acuífera*, and *A. coriophylla*; two *Compositæ*, *Vernonia bahamensis* and *Salmea petroboides*; one Passion-flower (*Passiflora pectinata*); *Oroton Eluteria*, *C. Cascarilla*, and *Argithamnia sericea* in *Euphorbiaceæ*; in *Orchideæ*, *Bletia purpurea* and two or three *Epidendrums*; *Jacaranda bahamensis* in *Bignoniaceæ*; and *Phialanthus myrtilloides*, and *Stenostomum myrtifolium* in *Rubiaceæ*. The non-endemic plants of the group may be classified in three groups:—

1. Characteristically West Indian types.
2. Widely spread tropical American types.
3. Cosmopolitan weeds and shore plants, such as *Suriana maritima*, *Ximenia americana*, and *Ruppia maritima*. Each of the three is largely represented.

The Collection of Baron Eggers.—The collection of Baron Eggers was mainly made in the small island of New Providence, where the capital (Nassau) is situated, and as this was also the case with the plants of Mr. Brace, a large proportion of the species are identical. The two collections supplement each other very usefully, for the shrubby plants of the Bahamas often show evidence of a considerable amount of such alteration as is produced by greater exposure, and in several genera (for instance, *Erythroxylum*, *Eugenia*, *Psychotria*, *Ficus*, and *Coccoloba*) it will be needful to have further specimens of the New Providence types before it can be safely decided what their relations are with the Cuban or the Jamaican species. One of the most interesting plants Eggers has gathered is the *Achras*, figured by Catesby (vol. ii. t. 87), which is evidently distinct specifically from the well-known *Achras Sapota*. He has added to the Bahaman flora the Rhamnaceous genus *Reynosa*, known previously in Florida. He has found a new species of the Mutisiaceous genus *Anastrophia*, of which several species are known in Cuba. In *Schæpfia Buxus* and *Linum* he has obtained full material of new endemic Bahaman species before known imperfectly. In a few cases his material shows that species supposed to be endemic are not really distinct. For instance, he has connected *Croton Hjalmarsonii* of Grisebach with the widely spread *Croton lucidus* of Linnæus.

Economic Bahaman Plants.—The group produces several interesting plants of economic value. Of these the principal are—

Mahogany—*Swietenia Mahogani*.

White Cinnamon—*Canella alba*.

Lignum vitæ—*Guaiacum sanctum*.

Sabicu—*Lysiloma Sabicu*.

Cascarilla Bark—*Oroton Eluteria*.

“ “ *Oroton Cascarilla*.

“ “ *Sideroxylon mastichodendron*.

Further Exploration.—Out of the twenty islands we can only look upon New Providence, which is a small island twenty miles long by seven miles broad, as at all adequately searched. Besides New Providence, Baron Eggers has collected a few species in Acklin's Island, Hog Island, Long Island, and Fortune Island. The five largest islands of the group are still nearly or quite unknown botanically. The island of Andros is nearly a hundred miles long by thirty miles broad, and has a mere fringe of population and a centre made up of forest and swamp. Abaco is nearly as long, but narrower and less promising. Eleuthera is the island in which pine-apples and other fruit are mainly grown for the American market. St. Salvador, the first land touched by Columbus, and the Great Bahama are both islands of considerable size, quite unknown botanically, so that there is abundance of work for future explorers.

Second Report of the Committee, consisting of Professors SCHÄFER (Secretary), MICHAEL FOSTER, and LANKESTER, and Dr. W. D. HALLIBURTON, appointed for the purpose of investigating the Physiology of the Lymphatic System. (Drawn up by Dr. W. D. HALLIBURTON.)

LAST year the committee appointed for the purpose of investigating the physiology of the lymphatic system presented a preliminary report dealing with the chemical physiology of the lymph cells as contained in lymphatic glands. They are able this year to present a report dealing with the same subject from a rather different standpoint. The work has been carried out by Dr. Halliburton in the Physiological Laboratory, University College, London.

Professor Schäfer and Dr. Halliburton have in the same laboratory commenced observations upon the movements of the walls of lymphatic vessels. This research is not, however, sufficiently advanced to enable the investigators to present a report as yet; they hope, however, next year to be able to continue their researches in this direction.

The following is Dr. Halliburton's report on the chemical physiology of lymph cells.

It was stated in the report presented last year that the following proteids are contained in the protoplasm of the cells of lymphatic glands:—

1. A globulin which coagulates at 48° to 50° C. *Cell-globulin a.*
2. A globulin which coagulates at 75° C. *Cell-globulin β.*
3. An albumin which coagulates at 73° C. *Cell-albumin a.*
4. An albumin which coagulates at 80° C. *Cell-albumin β.*
5. A peculiar proteid, with physical properties like mucin; with other characters like a globulin, and which was described provisionally as a *mucin-like globulin.*

These proteids are contained in extracts of the lymph cells made with various saline fluids, and can be separated by the usual methods of precipitation by neutral salts and fractional heat coagulation.

A few quantitative experiments have shown that the mucinoid globulin is the most abundant, and composes the greater part of the cell protoplasm; the cell-globulin β is the next most important quantitatively

of the proteids present. Cell-globulin α and the two albumins, especially the β variety, are present in only small quantities, and cell-albumin β seems to be often altogether absent.

Some further investigations upon the properties of the mucin-like proteid have led me to conclude that it belongs to a class of proteids called by Hammarsten¹ nucleo-albumins. These proteids resemble globulins in the way in which they are precipitated by salts, and also in their insolubility in distilled water. They, however, differ from globulins by yielding an ash rich in phosphorus, and on gastric digestion yielding an insoluble residue of the nature of nuclein, which is also rich in phosphorus. The substance was purified in the following way:—

An extract of the cells in 10 per cent. sodium chloride solution has a slimy mucus-like consistency; it filters very slowly, but it can be separated from the insoluble residues of the cells (nuclei, &c.) by filtration under pressure. On pouring this filtrate into a large excess of distilled water, the globulins are precipitated in a finely flocculent condition, and sink to the bottom; whereas the mucin-like proteid is precipitated throughout the water in the form of cohesive strings, which in a few minutes contract, and finally collect in sticky lumps which float upon the surface of the water. These were thoroughly washed with and kneaded in distilled water, and finally washed with rectified spirit and absolute alcohol. This substance after ignition yielded an ash rich in phosphorus. It was easily soluble in 1 per cent. hydrochloric acid; on diluting this solution fivefold or even tenfold with water there was no reprecipitation of the proteid.

A large quantity of such a solution in 1 per cent. hydrochloric acid was diluted till the strength of the acid was 0.2 per cent. On keeping this solution at the temperature of 40° C. in an incubator for twenty-four hours there was no precipitate; but on adding to it an active solution of pepsin there was in the course of three or four hours, at the same temperature, a cloudiness, which became denser, and ultimately a flocculent precipitate formed. This did not tend to disappear or become lessened after very prolonged digestion; it could not, therefore, be anti-albumid, the comparatively insoluble by-product which occurs in the digestion of ordinary albumin; for anti-albumid is, after prolonged digestion, largely converted into peptones.

This precipitate was collected, washed with 0.2 per cent. acid, and then distilled water and alcohol. It was soluble in alkalis (e.g., baryta water), and it also yielded an ash rich in phosphorus.

The filtrate from which the precipitate had been removed contained albumoses and peptones, the usual products of gastric digestion, and contained the merest traces of phosphorus. No such precipitate was produced by pancreatic digestion.

It is on these results of gastric digestion, as well as on the other physical and chemical characteristics of this substance, that I am inclined to include this proteid among the nucleo-albumins. Similar mucin-like globulins have been separated by Hammarsten from the cells of the sub-maxillary gland, which contain, however, true mucin in addition; from the synovial fluid and from bile, where they have long been mistaken for mucin.

With regard to the remaining proteids in lymph cells, I have not

¹ *Zeit. Physiol. Chem.* vol. xii. p. 163.

made out anything in addition to the facts I have already given (see last year's report), with one exception, viz., the heat-coagulation temperature of cell-globulin β is, as there stated, 75° C. when it is dissolved in a magnesium sulphate solution, or in a solution containing a minimal quantity of sodium chloride; but in a solution in which 5–10 per cent. of sodium chloride is present the temperature of heat-coagulation falls to about 60° C.

The next subject to which I directed my attention was the influence of these various proteids on the coagulation of the blood.

The proteids were separated in the manner already detailed, excess of salt removed by dialysis, and their influence on coagulation tested by adding them to dilute salted plasma, to hydrocele or pericardial fluid, or to vein-plasma obtained from the jugular vein of the horse by what is known as the 'living test-tube' experiment.

A complete communication on this portion of the subject has been sent to the 'Journal of Physiology,' but the main results of the investigation are as follows: their especial importance is the light they throw upon the nature of the fibrin ferment.

1. The only proteid in the cells which has any effect in hastening the coagulation of blood-plasma is the cell-globulin, which coagulates at 75° C. This substance, in fact, acts like fibrin ferment.

2. Fibrin ferment, as extracted from the dried alcoholic precipitate of serum (Schmidt's method of preparation), is found on concentration to be a globulin with the properties of cell-globulin.

3. The fibrin ferment, as extracted by saline solutions from what was termed 'washed blood-clot' by Buchanan, is a globulin and this globulin is also identical with cell-globulin.

4. Serum globulin, as prepared from hydrocele fluid, has no fibrinoplastic properties. It may be better termed *plasma-globulin*.

5. Serum globulin, as prepared from serum, has marked fibrinoplastic properties. This is because it consists of plasma-globulin *plus* cell-globulin, derived from the disintegration of white blood corpuscles, which are in origin lymph cells.

6. The cause of the coagulation of the blood is primarily the disintegration of the white blood corpuscles, and, perhaps, also of the blood tablets; they liberate cell-globulin, which acts as a ferment, converting fibrinogen into fibrin. It does not apparently become a constituent part of the fibrin formed.

Wooldridge's theory of coagulation, which makes lecithin the chief agent in the process, is not considered tenable; full reasons are given in the communication to the 'Journal of Physiology'; the essential objection to that theory is, however, this: it rests upon observations chiefly made with peptone-plasma, which is a very abnormal form of plasma. The precipitate produced by cold and the influence of lecithin in hastening coagulation, as described by Wooldridge, cannot be demonstrated with salted plasma, nor with vein-plasma: observations upon this latter form of plasma are of especial importance, as it is unmixed with any foreign substance. On the other hand, the addition of cell-globulin to this plasma hastens its coagulation very considerably.

To the cell-globulin theory an objection might be urged that the ferment and the globulin are not identical, but only closely associated together. This objection cannot at present be fully met; if, however, the two are not identical but only combined, it must be admitted that the

association is an exceedingly close one; none of the methods adopted for preparing the globulin pure separate it from the ferment. Until some method is shown by which any substance can be separated into two, we are not justified in saying that it is other than a single substance. Certain facts, however, of which the two most important are the action of alcohol and the action of heat, go far to prove that the ferment is the proteid.

The action of alcohol.—The ferment is precipitated by alcohol; and it is generally stated that, unlike proteids, it is not rendered subsequently insoluble in water by the prolonged action of alcohol. It is this fact upon which Schmidt bases his method of preparing the ferment, viz., extracting with water the dried alcoholic precipitate of serum. Hammarsten, however, has noticed the loss of activity which the ferment undergoes after exposure to the action of alcohol; and in the present research it was found that an exposure of the ferment to the action of alcohol for six to seven months renders it absolutely inactive. The ferment is thus, like proteids, rendered ultimately insoluble by alcohol, though more slowly than ordinary albumin is.

The action of heat.—The most striking fact that goes to prove the identity of the ferment and proteid is that the activity of the ferment is abolished at the same temperature as that at which the distinctive characters of the proteid are destroyed (about 75° C.).

Granting that the ferment is a proteid, it is undoubtedly a globulin: it is insoluble in distilled water, as Gamgee first pointed out when he prepared it from what was termed by Buchanan 'washed blood-clot.' The apparent solubility in water of the ferment prepared by Schmidt's method is due to the fact that a portion of the salts in the ferment powder enters into solution at the same time. If the ferment powder be first subjected to prolonged washing with distilled water, and finally to dialysis to remove the salts, a watery extract has then little or no ferment action, while a saline extract has powerful ferment properties. The ferment action of such a solution is lessened but not destroyed by dialysis: this is apparently due to the fact that even prolonged dialysis is never sufficient to precipitate all the globulin in a solution.

The proteids of the cells of the thymus gland.—This gland is a structure which histologically is very similar to lymphatic glands. I have made a few experiments with the object of determining whether the resemblance is borne out from a chemical point of view also.

My observations under this head will be of a preliminary nature only, as the experiments are not at present completed. The chief points I have made out are the two following:—

1. That the greater part of the cell-protoplasm is made up of a nucleo-albumin with properties similar to those already described.

2. That a globulin coagulating at 75° C. is the next most abundant proteid present. This has fibrino-plastic properties exactly similar to those already described as belonging to the cell-globulin derived from the lymphatic glands.

*Report of the Committee, consisting of Professor T. G. BONNEY, Mr. J. J. H. TEALL, and Professor J. F. BLAKE (Secretary), appointed to investigate the Microscopic Structure of the Older Rocks of Anglesey. (Drawn up by the Secretary.)*¹

[PLATES II.-V.]

THE rocks which form the subject of the present report have already received the attention of geologists, and some eighty or ninety of them have been described by Professor Bonney, mostly in appendices to various stratigraphical papers by other authors.² They have also been examined and used for stratigraphical purposes by the Secretary.³

The present object, however, is to study them for the information they may give on the nature and cause of the metamorphism to which many have been subjected, and to determine how far their microscopic structure may throw light upon their origin. Their special interest lies in the fact that the series includes both altered and unaltered rocks, as also foliated and non-foliated, and hence gives promise of throwing some light on the connection between them.

Although the work already done upon the rocks of Anglesey has not been of a systematic character from this point of view, being limited to the determination of the particular nature of individual rocks, yet, as could not fail to be the case, many valuable observations of general interest have been included in these descriptions. Moreover, the rocks at St. Davids, which are in part the equivalents of these, and to some extent of the same character, have been dealt with from a general point of view by Dr. A. Geikie,⁴ whose conclusions may be usefully compared with those of this report.

For the purposes of study the older rocks of Anglesey may be divided as follows:—

1. Rocks which on stratigraphical grounds are generally considered sedimentary, including volcanic contributions.
2. Rocks of special origin.
3. Crystalline rocks which may be of igneous origin.

In referring to the localities whence the rocks are derived, and in indicating their general stratigraphical relations, those subdivisions will be adopted which are laid down in the paper above referred to on the Monian system. It is there shown that those rocks in Anglesey which are at least older than the Ordovician lie in six distinct areas, which are severally called the Western, Central, Eastern, and Northern Districts, and the districts south of Traeth Dulas and north-east of Parys Mountain. The series of rocks which lie to the south of the fault which divides Holyhead Island is spoken of as the South Stack Series. The Central dis-

¹ The other members of the Committee wish it to be understood that, as this report deals with subjects on some of which there is much controversy, Professor Blake is solely responsible for the statements therein contained.

³ *Quart. Journ. Geol. Soc.* vol. xlv. p. 463 *et seq.* The further study of these rocks has, in a few instances, led to a slight modification of some of the petrographical statements in that paper.

⁴ *Quart. Journ. Geol. Soc.* vol. xxxix. p. 261 *et seq.*

trict is divided into two—the Eastern and the Western portions—by a line running along the west boundary of the grey gneiss.

ROCKS OF SEDIMENTARY ORIGIN.

The study of these has reference, first, to their mineral constitution; secondly, to their original structure; and, thirdly, to their alteration.

1. *The Minerals of the Sedimentary Rocks.*—The greater number of these may be said to belong to the acid type, the ordinary constituents of basic rocks being comparatively rare.

Quartz is the most abundant mineral of all. If we except the limestones and other special rocks, there is hardly another in the whole series in which, when the minerals are recognisable, quartz is not among them. It occurs both authigenetically and as derived fragments. In the latter case it sometimes contains needles of apatite, as in the quartzite of Holyhead Mountain (1), and sometimes fine needles of rutile, as in the slates of Roscolyn (66). It usually has numerous bubbles, which mostly occur along cracks, and these cracks are often continuous from one element to another, and must therefore have been produced in the quartz after it had been placed where it now is. Some of the derived fragments of quartz, however, have their lines of cracks terminating at their boundaries. Occasionally the silica along broad bands is chalcedonic, as at Peniel (11), and more rarely small rounded fragments of bluish tint may indicate opal.

Felspar.—In the absence of any structural lines it is often impossible to do more than determine the family. When felspar and quartz are associated, and both are of minute size, it is often difficult to distinguish between them. In the quartz the inclosures may generally be recognised as bubbles, in the felspar as dust or small crystals. When, however, both are water-clear and too small to give any reaction in convergent polarised light they can only be distinguished by the slightly higher refractive index of the quartz, which makes it stand out from the felspar when both are together. The larger crystals of felspar present a very characteristic phenomenon. (See fig. 1.) They are filled with minute flaky or tabular small crystals. These may be arranged in intersecting lines, or be quite irregular. They are often of considerable relative size, as in the derivative fragments in the mica schists of the Eastern district (151). Whether the small crystals are original inclusions or results of decomposition is difficult to say, but their general character and arrangement seem to indicate the latter. Such 'speckled' felspars are not always indeterminate, but are often banded plagioclase; they are almost invariably derivative, or at least of an older generation than the bulk of the rock. This speckling seems to be a further stage to 'schillerisation.'

Plagioclase.—The banding which is presumed to characterise the plagioclastic group of felspars may have more than one origin. Professor Judd¹ has recently suggested that in some cases it is brought out by pressure. There are numerous instances in these Anglesey rocks, as at Bodlew (148), of the bands being continuous across only half of the crystal. In these cases they are less regular and distinct. When two such series of lines cross at right angles we get the phenomena of microcline; but in this also there is great irregularity—the bands die out and change position as the slide is rotated. Such are seen in the grey gneiss of Gwalchmai (69) and at Ty Gwyn (188), but they are better shown in

¹ *Mineralogical Mag.* 1888.

Fig. 1. (151)

Fig. 2. (81)

Fig. 3. (5)

Fig. 5. (75)

Fig. 6. (150)

the rocks of igneous origin. In these cases it cannot be considered true twinning which produces the bands, but a reconstruction under pressure of a single mineral. There are, however, in numerous rocks small angular fragments, in which the lines of twinning have the utmost regularity and definition—*e.g.*, at Llaneilian (223). These are probably true plagioclase. As far as observed they invariably are derivative, being angular and isolated, and often lie transverse to the general direction of foliation.

Mica.—The most characteristic species of this family observed in the sedimentary rocks is muscovite. It is colourless for all rays, and polarises vividly. It is commonly of small size, but is best developed where the other elements are large, as in the gneisses and mica schists of the Eastern and Central districts. It also occurs as large fragments in the midst of a non-micaceous matrix in the slates of Roscolyn (67), and the quartzite of Porth-yr-Ogof, Holyhead (4). Inclusions are rare, but in a rock full of mica, on the Llanerchymedd Railway (93), the larger elements are full of other crystals, thus resembling a speckled felspar.

Chlorite.—It appears that two distinct species have been referred to under this name, the only common characters being greenness and transparency. The true chlorite is more or less amorphous, and occurs in large sheets as well as more fibrous masses. It often forms the whole groundmass of the rock, as at Bryn Minceg, near Llandegfan (189). It also occurs as beautiful vermicular aggregates amongst the large vein substance, as in the mica schist of Bodowyr (146) and Gaerwen (160); and occasionally it crystallises transversely in a lenticle, as at Roscolyn (67). In these cases it has very little polarising power, remaining nearly dark between crossed Nicols, or giving bluish and purplish tints. There is not much of such chlorite in the Western district, but it is more abundant in the Eastern, where also epidote more commonly occurs, after which it is often found as a decomposition product, as in the rock at Hafodty (145).

Green-mica.—This is the so-called chlorite of the Western district, being the essential ingredient in the 'chloritic' schists. It occurs in long thin crystalline flakes, with parallel sides but imperfect terminations, and may be either isolated or aggregated in groups. It is transparent and greenish in tint, and extinguishes parallel to the trace of cleavage. The polarisation colours are either brown or fairly brilliant tints of red and green. It is often surrounded by the true chlorite as by a decomposition product.

Sericite.—This term is applied to the colourless strings and broader patches in which no individuals can be distinguished, but which polarises in fairly brilliant colours between crossed Nicols. It occupies the cracks and minute interstices between the other elements, and is especially characteristic of rocks which have been partially disintegrated by pressure.

Epidote.—It is generally supposed that this species is a decomposition product from felspar. In the sedimentary rocks of Anglesey there is no special evidence that this is its direct source. It is here always highly fractured and more or less dusty, and occurs in isodiametric patches without crystalline form. It shows high polarisation tints in the centre, which change rapidly towards the edges, owing to the thinning off of the grains. It gives rise by decomposition to dust of a characteristically crystalline aspect, by which it may be recognised even when too small or decayed to show colour between the Nicols. It is most abundant in

the Eastern and Northern districts; occurring in the former in the laminated schists often imbedded in chlorite, as at Hafodty (145), and also as rounded derivative grains in the newer dust rocks, which is its principal mode of occurrence in the sedimentary rocks of the north.

Kaolin is perhaps the best name to apply to the white amorphous dust which is so abundantly scattered over the great majority of rocks, lying either in isolated grains in the less completely crystallised bands, or pushed aside into the interstices between well-formed crystals. In the former case it may be pretty nearly in its original position of deposit; in the latter, it is either the residuum which has refused to crystallise, or the relics of former crystalline substances which have since disintegrated. There is, however, no evidence as to its chemical composition, though kaolinite in definite crystalline forms has been discovered some time ago in the slaty rocks of the Northern district.

Pyrites occurs in well-formed, usually cubic crystals, in rocks of very fine grain in the Northern and Central districts. It does not seem very certain whether these are derivative from older rocks or authigenetic, though the latter seems more probable.

Ferrite is sometimes seen surrounding the pyrites as a red translucent decomposition product; but the substance usually quoted by this name consists of a brown amorphous dust found in similar circumstances to those of kaolin, but in more basic rocks.

Garnet occurs in rounded, worn-looking, or imperfectly formed crystals in the mica schists of the Eastern district, as near Gaerwen (156). They are here so abundant that in spite of their numerous cracks, filled with a later crystallisation, there seems no evidence of their being derivative, the whole rock being completely crystallised. These are generally of a pale green tint.

Zircons, in characteristic short prismatic crystals with worn pyramidal ends, are tolerably abundant in some of the quartzites, as at Porth-yr-Ogof (2). Here they are certainly derivative. They also occur in the mica schist of Abersant (19) and in the quartzitic rocks of the South Stack series (64, 65); also in the quartzose gneisses and quartzites of the Central district, as at Gwalchmai (70) and Bodafon (109); but they have not been observed in the sedimentary series either of the Eastern or Northern districts. Possibly these latter were derived from a different source.

Such are the principal minerals which enter into the composition of the oldest stratified rocks of Anglesey. Others, such as sphene, rutile, apatite, and tourmaline, are either very rare, occur only as enclosures, or are doubtfully determined.

2. *The Structure of the Sedimentary Rocks.*—The present structure of the rocks depends in part on their original constitution, and in part on the alterations which they have undergone; but it is not always easy to determine which of these has most influence on the observed results. Some of the rocks are crystalline, and are undoubtedly much altered; others are composed of dust or fragments, and these may be either original or the results of crushing *in situ*. In this case their probable origin must be sought in their stratigraphy; and by examining the structure of those rocks which are thus proved to be original, and comparing it with those in which crushing may have had a considerable effect, we may obtain characteristics which shall be of avail when stratigraphy gives doubtful information. So far, then, as may be judged by their strati-

graphy, the original rocks may be classified as follows: (1) rocks composed of uniformly small elements; (2) rocks of larger grain; (3) rocks with larger fragments imbedded in a finer matrix; (4) laminated rocks.

In the study of these we have to determine, as far as possible, the criteria by which we may distinguish—(1) original fine dust from the results of crushing or decomposition; (2) fragments of minerals obtained from earlier rocks from crystals formed *in situ*, and from fragments produced by crushing; (3) lamination from foliation.

In determining these points it will be well to lay down beforehand the principles of interpretation adopted, most of which are, of course, well known, and only need to be definitely formulated. In addition, however, to ordinary methods, a plan of observation, not as yet, so far as I am aware, applied to the microscopic sections of rocks, has been found of great value—viz., the use of a paraboloid with a binocular microscope. The appearance of a rock, when examined in this way, is of course very different to that between crossed Nicols, or even by plain transmitted light; but the structure is sometimes shown with a clearness which is quite astonishing. Everything in the interior capable of reflecting the light is brought out brilliantly, and the perspective of the binocular shows the true relative position of such objects. If a rock contains fragments in the midst of authigenetic elements, it will very seldom happen that the union of the two will be complete, and thus the boundary of the fragment will be marked by a reflecting border; whereas the individual authigenetic elements being in optical contact the light passes through unbroken. The natural shade of colour, both of opaque and transparent objects, is also well brought out by this method; and the special characters of the cleavage of various minerals is indicated by the reflection of the light from their surface. The fine particles of dust are very clearly seen, whether isolated or in lines, and by the peculiar glistening they may be distinguished, however minute, as crystalline or amorphous. The characters of individual minerals as seen in this way are not very describable, but when once the general aspect has been seized, the minerals are easily recognised and their presence is immediately revealed.

The distinction between original dust and that produced by crushing or decomposition is not perhaps always very clear; but if there has been crushing it will seldom, if ever, happen that none of the other signs, to be hereafter described, shall be present. If the dust be aggregated in the forms assumed by authigenetic elements, either such as they had at first, or such as may have been superinduced, it may be assumed to be due to the decomposition of such. But when it is scattered about irregularly, or lies in loose bands of indeterminate form, there can be little reason for considering it as anything but original.

The distinction of authigenetic elements from fragments when both are crystalline is not in all cases possible. Both may be so small as to present few characters for discrimination, or the metamorphosis may be carried so far as to absorb the boundaries of the fragment, and make the outside practically authigenetic. In general, however, we may rely upon the following criteria. A fragment in an altered rock being less easily absorbed, according to its size, will generally be a larger isolated element in the midst of a minuter groundmass. Authigenetic elements being formed from a magma which is capable of motion and mixing, will generally be uniformly distributed throughout the mass; hence a stray

element of a common mineral, such as plagioclase, amongst abundant elements of another character, may be considered to be a fragment. This will not, of course, apply to such minerals as are always more or less sporadic, and are known to be products of alteration, such as garnets. The most important distinction is the following. The outline of a fragment may be rounded or angular, and the shape in the latter case may be peculiar, especially if the rock has been compressed; but when the elements are forming authigenetically in a rock the crystallisation will set up at two or more neighbouring spots, and the growth of the crystals will continue till they meet. The line of junction in this case may be and often is an exceedingly irregular one, curving in and out like the lines of junction of two bones which ossify from distinct centres. In the case of bones such junctions are called sutures, and we may therefore conveniently describe the similar junctions between crystals as *sutural*, and define this well-known peculiarity by stating that sutural junctions are characteristic of authigenetic crystals. (See fig. 2.)

The distinction between fragments of sedimentary origin and those produced by crushing is in general easy if the crushing has taken place subsequently to the crystallisation, for it can very seldom happen that absolute resistance and absolute yielding to the crush can be found side by side; hence crushed fragments are in groups obviously once united into a larger element, but fragments of sedimentary origin are entirely independent; and the same difference may also be of assistance when crystallisation has succeeded the crush.

Lamination may be confounded with foliation when the latter is parallel to the bedding, as seen on the large scale; but the essence of lamination is the alternate occurrence of different kinds of mineral substance in the bands. Now, unless there has been confusion of the substance of a rock, far beyond the point of contorting the laminæ, these original differences will have their effect upon the result even when the rock is crystalline, for one kind of crystal will be more abundant in alternate bands, and the least easily crystallisable will remain as dusty fragments, which will also lie scattered between the crystals along the same lines. Such phenomena, which are quite distinct from foliation or the orientation of crystals, are taken to indicate original lamination. (See fig. 3.) The principal case in which doubt arises is when the rock, though composed of a uniform substance, is more separable along the line of deposit, and clean crystallised quartz has segregated out in this direction and given rise to an apparent alternation.

The Rocks Composed of Uniformly Small Elements are probably much more numerous in the oldest series in Anglesey than would be gathered from a comparison of the numbers described in the present report, since few of them would tempt microscopical examination. Yet, excluding those which contain larger fragments, 84 out of 168 of the sedimentary rocks examined have this character. In the Western district this type of rock is largely developed. In four instances it consists of practically unaltered dust. One of these is an indurated purple shale or slate, well bedded, and passing into chloritic schists. It occurs on the east side of the Holyhead Straits (7). There is a certain amount of irregular parallelism in the dust, and there are a few irregular cracks filled with quartz; but otherwise there is nothing to show that the rock has suffered any change beyond an ordinary compacting by superincumbent pressure. This is a remarkable case as occurring in the lower part of the series. The other three belong

to the unstratified portion, to which a more or less volcanic origin is assigned; in fact, they are indurated tuffs. These are the green rock at Peniel (11), the unstratified yet feebly false-bedded tuff of Church Bay (29), and the dust rock at Pant-yr-Eglwys (34). The remaining fine-grained rocks in this district show more or less metamorphism, the greatest amount occurring nearest to Holyhead Island. Of these may be cited the rocks at Caer Ceiliog (9) and Bodedern (23), also from near Llanddeussant (20, 25), Llanfachreth (18), Llanfaethlu (27), and Llanrhyddlad (30). These are in parts of the series which are far separated from each other on stratigraphical grounds; but there is little to choose between the rocks. Another, dynamically altered, occurs at Porth Dryw (12). Only one of this type has been examined from the South Stack Series at Porth-y-crug (62).

In the Central district the fine-grained rocks occupy two distinct positions. In the western portion the mass between the granite areas at Llanfaelog (82, 83) is of this type (though much metamorphosed), and so are almost all the rocks examined between Bodafon and Llanerchymedd. One near Chlorach Bach (103) is highly calcareous; the others, from Trewyn (104), Clegyr (108), and the west side of Bodafon (110), are more crystalline. In the eastern portion there is a longitudinal band of such rocks from Cerryg-ddwyffordd (98) to Llangefni (100), and so on, to the banks of the Cefni, half-way to Llangwyllog (102).

In the Eastern district a fine tuff occurs in association with the igneous rocks at Gwladys (208), but the remainder belong to the stratified series, and are chiefly found along the eastern edges, as at Bodlew (147), Cadnant Vale, near Menai Bridge (187), Clawdd-y-parc, near Llandegfan (196), Ty-garw, near Beaumaris (195), and Tyddyn, north of Beaumaris (199). In all these places they have become finely crystalline. The only place in which the dust may be suspected of being produced by local crushing is on the north-eastern edge of Malldraeth Marsh (190). Dust rocks of doubtful character, which appear to have undergone only a slight chemical or infiltrational metamorphosis, occur at Llyn Bodgolched (198), in the road between Garth Ferry and Beaumaris (192), and in the country behind this road (191); in the latter case the rock is full of derivative epidote. In the Northern district so many of the rocks have a slaty aspect that few have been examined. Most of them, however, contain larger fragments, and two only have been found free from them—viz., at Mynydd Mechell (212) and Bodewryd (220). Both of these have become minutely crystalline.

It will thus be seen that only six out of the thirty-four examined can be said to be in any sense unaltered, and many of them are completely crystalline. This is entirely in conformity with the observations of Dr. A. Geikie on the rocks of St. Davids, that 'certain layers or particular kinds of fine detritus, more especially some of the finely comminuted volcanic dust, have been specially susceptible of change.'

Rocks of Coarser Grain may arise either from the running together of the materials of finer rocks in the process of crystallisation—and such must be omitted for the present—or from the original elements being larger. The interest of these latter arises from the fact of their association with the finer rocks, after the manner of ordinary sediments, and from the greater difficulty in their metamorphism leaving them more unaltered. Thus, on the west side of Cemmacs (216) we find a rock of which one half is fine-grained and the other half coarser, composed of

well recognisable grains of quartz and felspar. So at Bodafon (106, 107) and Ty Croes (85) coarser and finer rocks are associated. In the Eastern district we find such at Wugan (201), and at Pen-y-parc, Beaumaris (193), where the original fragments were recognised by Professor Bonney. The most characteristic occurrence, however, of these coarser rocks is in the South Stack Series. In this group there are numerous unexamined fine-grained rocks, but almost all those which have tempted examination have turned out to be gritty in character, the original quartz grains being closely packed and very uniform in size. Of these may be cited as examples the rock from the bottom of the gorge at Gogarth (59), and a flaggy bed at the lighthouse steps (60); also one from Porth-dafarch (61), and one from Porth-y-crug, near Roscolyn (63). Even when there are larger fragments imbedded the groundmass of these rocks is of a coarser character, as in the quartzites of Porth-y-gwalch (64) and of Roscolyn (65), and in the neighbouring darker rocks (66). The rocks, therefore, of this series are as well marked by their microscopic structure as regards their original composition, as they are by their bedded character as seen on the large scale.

Rocks containing Larger Fragments in a Finer Groundmass.—These fall into several categories—those in which the principal part is groundmass of minute elements, with only a few of the characteristic fragments scattered here and there; those in which the fragments constitute the principal part, and the groundmass is reduced gradually to a minimum; and those in which the groundmass is also of coarse elements. The first of these groups, in which the fragments are comparatively rare, approximate very closely to the finer-grained rocks, especially when both have undergone crystallisation. Such are well seen in the eastern end of the Northern district—as at Pengorhwyfysa (222), Point Ælianus (224), and Llaneilian (223), where there are but a few angular pieces of quartz and felspar, possibly of volcanic origin. As we pass west, towards Pen-bryn-yr Eglwys, a focus of eruption, these fragments become more numerous, as at Llechog Ucha (221), in the slates between Llanrhydrus and Camlyn (213), at Mynydd Mechell (211), till they become most numerous near Llanfechell (219), forming a grit largely composed of fragments of quartz and felspar, and containing also pulled-out pieces of a minutely crystalline substance. This is the rock of which Prof. Bonney recorded that it contained almost certainly fragments derived from the older series. It does not, however, seem certain to the writer that these pieces are anything more than a peculiar vein substance, such as occurs in several rocks, and in some cases they may be decayed and reconstituted felspar. In the Western district, besides the laminated rocks, to be described further on, there are several of this group associated with the finer-grained rocks, as at Caerdeon (24), beyond Porth Dryw (13), and in the tuffs of Church Bay (28). In the other districts only one of this group has been met with—viz., in the northern part of the Eastern district, at Coedmawr, near Llanfaes (200). It is suggested that these fragments for the most part are volcanic ejectamenta, contributed to the finer deposits, in which there is in general a complete absence of stratification either on the large or the microscopic scale.

The group with abundant fragments in a less abundant groundmass has not been observed in the Northern district, which was probably further removed from the sources of eruption, but in the other districts such rocks are numerous and important. In the Western district two of great interest

have been examined from the crossing of the river Alaw on the road to Llanfachreth (10), and from near Llanfaban (22). They are decidedly of a more basic type. They contain few fragments of quartz, but abundance of feldspathic fragments, sometimes of fresh banded plagioclase, sometimes speckled, and sometimes entirely passed over into sericite. There are also fragments of the finer crystalline material, as at Llanfechell, with minute crystals of green-mica in a clear groundmass; also of quartz vein stuff, and much epidote; possibly also olivine and magnetite. One is tempted to ask if these can be in any way connected with the eruption of gabbro, which took place not very far to the south. Another rock, whose numerous fragments are mostly quartz, and the matrix the usual fine-grained material, occurs in the hill over Ogo Lowry, near Llanrhyddlad (31), which has fragments of volcanic rock similar to that which forms the agglomerates occurring within little more than a mile. In the Central district the rocks with abundant fragments are an important group. They occur associated with the dust rocks at Cerryg-ddwyffordd (99). Here there is very little matrix at all, the fragments of felspar are more numerous than those of quartz, and there are a number of dusty fragments which may be in some cases devitrified lava, in others lapilli of tuff. This is one of the rocks described by Professor Bonney, who suggests the same origin. Further south the rocks are seen to contain, scattered irregularly through them, nodular hard masses. A microscopical examination of one of these (89) shows they are places of aggregation of the large fragments of quartz and occasionally of felspar, so closely packed as to leave scarcely any room for matrix, which consists of amorphous chlorite only. At Dinas Llwyd (126) the rocks of this group are similar to that at Cerryg-ddwyffordd, but contain also fragments of a dark rock, consisting of lath-shaped felspars in a black matrix, a type found *in situ* at Gwalchmai. In the Eastern district two rocks with abundant fragments have been examined. In that from Ty Gwyn, near Menai Bridge (188), the fragments are of quartz and plagioclase, with beautiful banding, set in abundant matrix, much modified by pressure. In the other, from Bryn Minceg, near Llandegfan (189), the fragments are smaller and are embedded in abundant chlorite. This also has suffered from pressure.

The group in which the groundmass is also of coarse elements includes the various quartzites. In that of Holyhead Mountain (1) the groundmass is so altered that it is difficult to distinguish the smaller elements as derivative or authigenetic. The larger fragments are of all sizes, varying from such as are scarcely distinguishable from the groundmass up to large pieces .04 inch in diameter, all except the little zircons being of quartz. In the quartzites at Porth-yr-Ogof (2, 4) less change is apparent, and the groundmass consists of tight-fitting fragments, with only room for a little green-mica between, and the large fragments are less numerous and conspicuous. At the junction with the chloritic schists (4) there is an appreciable admixture of felspar fragments. The rock in the centre of the island (3), though it contains more green-mica in the interstices, more resembles the quartzites of the South Stack Series in having little differentiation between the sizes of the fragments; but it is allied to the Holyhead quartzites by its zircons, and it contains also felspar fragments. It is not, therefore, so homogeneous as the rocks of the South Stack Series. The great masses of quartzite at Bodafon (109) and Craig Fryr (111), however different they may now be, were originally

of similar type, though the general size of the elements was smaller, and the larger fragments are fewer; but they are characterised, as at Holyhead, by their zircons and possible tourmalines, and other peculiar but uncertain minerals.

Laminated Rocks, as defined by the alternation of different materials in bands, are not abundant in Anglesey, but when present they are easily distinguished. They occur only, as far as observed, on one horizon—namely, immediately above the quartzites or equivalent rocks, where the series is complete; they are thus confined to the Western and Eastern districts. Their structure is admirably seen in the rock from Porth-y-felin, Holyhead (5), in which the laminæ are beautifully bent. The rock is now a highly crystalline one, with green-mica distributed abundantly throughout; but in certain narrow, well-marked lines it becomes much more abundant, and has granules of dust-like epidote mixed with it. Any one of these bands may be traced continuously from one end of the slide to the other, always keeping its distance from the next, and following every bend in the rock. These bands are of different thicknesses and separated by different intervals; about twenty of each may be counted in half an inch. The principal part of the rock is quartz, but a few fragments of plagioclase are scattered here and there. There are seldom any phenomena indicating pressure after the formation of the rock. These features indicate a true laminated original deposit. In another example, from Porth-yr-Corwgl (6), we find the same alternation of more and less micaceous and dusty bands, but here a later pressure has been at work. It has, however, only served to destroy the individuality of the crystals, and to intensify the difference between the bands. These are still continuous and equidistant, and the original fragments of quartz and felspar have not been obliterated. The rocks to the south of Porth-y-defaid (17) are also beautiful examples of this type; specimens occur which are neither contorted nor pressed, but simply altered by crystallisation, with the derivative fragments relatively large and abundant. It will be remembered that not far from here is the place of occurrence of the unaltered slate. The finer-grained rock from near the chapel, Four-mile Bridge (8), described by Professor Bonney as a 'normal schist,' shows the same lamination, but not quite so distinctly, the micaceous bands being broader, and their regularity somewhat interfered with by the introduction of segregation veins of quartz. It is, in fact, a somewhat intermediate rock between those of Holyhead and the fine-grained rocks to the north-east. Its lamination is clearly recognised by Professor Bonney, who says the rock 'has a banded structure, probably due to original bedding.'

In the Eastern district the only two rocks of this kind examined have suffered much disturbance, so that their laminated character is much more easily recognised with a hand-magnifier than with a microscope. In that from Tyn-y-mynydd, on Mynydd Llwyddiart (163), there are some bands less disturbed, and these are quite equidistant and continuous. They contain epidote in the lighter bands, and large plates of mica in the darker. Elsewhere they become more contorted. Both here, however, and at Hafodty (145) in the south, the peculiar character of the rock is nowhere lost.

All the above-named rocks maintain as their present essential character the structure they originally possessed, but there are a large number of others in which metamorphism has gone so far that its results are the

most conspicuous feature of the rocks, and yet not every sign of the original deposit has disappeared. The last things to disappear are the large fragments, which are usually of felspar, and often lie in a transverse direction to the general orientation. That these fragments are not 'eyes,' in the sense of being the only parts of a felspathic rock which has escaped destruction by pressure, may be gathered from their general occurrence also in the rocks already described, especially in the laminated rocks, and the probability of the origin in the two cases being similar. It may be added that there is usually no sign of pressure in connection with these fragments. They may rather be accounted for by the difficulty of their absorption and recrystallisation, owing to their size. The following may be cited as illustrations of these solitary fragments. In the cleaved rocks of Roscolyn (67) there are many large pieces of quartz and mica. In the Northern district the rock at Llanflewyn (210) has rather small fragments, including plagioclase. In the Central district only one out of five of the highly altered rocks examined contained any original fragments—namely, that at Porth-gwyfen (76), and these are of speckled felspar. In the Eastern district, also, only a small proportion—five out of twenty-seven examined—show any fragments; and in only two are the fragments at all conspicuous—namely, in peculiar rocks near Berw Ycha, south of Holland Arms (152). These fragments are of quartz.

From the above descriptions it will be seen that a large proportion of the older rocks of Anglesey, obtained from all parts of the series, still retain unobliterated their original structure, though it has been altered by later actions of several kinds. These original structures vary, as do the ordinary deposits of later date, and show us fine muds, coarse grits, and volcanic accumulations intermingled one with another, and with intermediate types of deposit. These form a fixed starting-point, whence we may set out on our examination of the metamorphism of the region.

3. *The Alteration of the Sedimentary Rocks.*—Although that group of rocks which on stratigraphical grounds is considered to be the oldest shows the most complete metamorphism, it does not appear to be a general rule that the amount of change in a rock of the series being studied is proportional to its age. The amount of alteration appears, in fact, to depend in part upon the constitution of the rock, and in part upon accidental circumstances, amongst which latter may, perhaps, be included the intrusion of vast masses of granite. The rocks which have most resisted alteration have been either very fine-grained rocks, which may possibly have been impervious, and those in which the fragments have been so closely packed that there has been little room for matrix between. The least amount of alteration of a chemical kind consists in the introduction of a little green mica or sericite into the original interstices, and very few rocks have escaped this amount. The interest, however, arising from the alteration commences when it is carried further.

In this case we may consider separately the alterations which are of chemical, and those which are of mechanical, nature. The chemical alterations are those which bring about the crystallisation of the materials *in situ*. With the cause of the chemical alterations itself we need have nothing at present to do. The crystals arising in the rock, if they possess one axis longer than the other, as is usually the case, may have this axis constantly fixed throughout the rock in approximately the same direction. In this case the elements are *orientated*; but if there is

no longer axis, or the different crystals are arranged in different directions, there is no orientation. The latter of these two alternatives is usually confined to igneous rocks; and hence we find that such sedimentary rocks as are not orientated have isodiametric elements, and thus form a mosaic. The term mosaic felspar has been used when the elements belong to that family, but there are other minerals of the same habit, under similar circumstances, so that we may extend the term and speak of *mosaic rocks*.

The mosaic rocks arise principally by the alteration of those of fine original grain, and form a very characteristic group. We may take as examples of these the rock at Llanfaethlu (27), Llanrhyddlad (30), and the hill over Ogo Lowry (32) (see fig. 4). When the most unbroken parts of these are examined with the paraboloid they are seen to consist of a transparent mass, in which there float very minute specks of reflecting matter. These specks are comparable in size with the finest cavities in quartz, or those which give a slight opacity to a translucent felspar. Where the grain of the rock is smallest, the specks appear uniformly distributed; but in the slightly coarser parts they are aggregated into minute patches separated by clearer lines. These aggregates are seen between crossed Nicols to represent the individual crystals, and when they appear uniformly distributed the crystals are too small to be individualised. Amongst these may float more or fewer crystals of chlorite, so minute as to be visible only under a high power, and quite indistinguishable between Nicols. This kind of rock appears specially liable to be cracked and torn—the cracks being of more than one age, and sometimes filled with larger crystals of quartz, and sometimes only with dust—and these again are twisted and bent. Such is the minute structure of the rock, which has been called a ‘marbled slate.’ It is of wide occurrence in Anglesey.

Very nearly allied to this type of altered rock are those which contain angular fragments in a fine groundmass. This groundmass has become a fine crystalline mosaic, but here and there is seen a peculiar kind of discontinuity which may be called a tension area. Such areas are more or less in the form of three-rayed stars of very irregular form, and they are occupied by elements of larger size than the rest. Now, wherever an ordinary crack traverses a rock, the elements with which it is filled up are of medium size; and therefore larger than the finest. We may suppose, therefore, that these irregular areas, which die out on all sides, represent spots where, as in cracks, the pressure has been relieved. Rocks showing this structure have been examined from near the river Alaw (22), at Caer-deon, near Llanddeussant (24), near Cemmaes (216), at Llechog Ucha (221), Pengorhwyfysa (222), Llaneilian (223), and Point Ælianus (224). In the last case there is an apparent orientation, but it is found not to affect the substance of the rock, but to be due to a number of later parallel cracks which have been filled with sericite. This is the ‘foliation oblique to the bedding’ of Sir A. Ramsay.

From these we are led on to a type of rock which is very difficult to explain. It consists entirely of unorientated elements of medium size, large enough to show sutural junctions. These are not all of one kind, but apparently consist of felspar and quartz in equal proportions. The best of these is the remarkable rock associated with the granite to the west of Gwalchmai (86), and usually called a *hállefinta*; except for its apparent bedding on the large scale it might almost be a felsite

Fig. 7. (155)

Fig. 12. (1)

Another in the district south of Traeth Dulas (140) is still more like a felsite. Others at Porth-ceryg-defaid (83) and north of Llangwilog (87) are so broken up that their origin is still more obscure.

We have next to study the introduction of orientation into this type of rock. Now orientation, as shown in the altered rocks of Anglesey, may be of several kinds. In a great number of instances it depends solely on the occurrence of flaky minerals. The lowest kind of orientation is when these flakes are scattered promiscuously amongst the other elements; but, wherever they may be, their long axes lie in the same direction. This may be called *quincuncial* orientation (see fig. 5). A higher kind is when such flaky minerals occur in definite lines. In this case there is often no perfect parallelism of the individuals, but they may make considerable angles with each other; yet the general direction is constant. It is this kind of orientation which produces the most perfect schists. It may be called *linear* orientation (see fig. 6). The highest kind is when the orientation depends not only on special minerals, but on all the elements, whose long axes are either accurately or generally in the same direction. This may be called *elemental* orientation (see fig. 7). In all these cases individual crystals are orientated; but there are other kinds of orientation seen only in the rock as a whole. Thus in some the elements of quartz and felspar, of which the rock is composed, though they may themselves be isodiametric, lie in bands side by side. From the similarity of the result to lamination we may call this *laminar* orientation (see fig. 8). In other cases no orientation can be observed in the small portion of the rock which comes under the microscope at one time; but when the slide is viewed with a hand-lens, there is seen to be a rough parallelism in the collocation of the more conspicuous elements. Such may be called *confused* orientation. Examples of all these forms of orientation will be found in the various rocks to be yet described.

False orientation, which does not affect the substance of the rock itself, is that produced by a series of parallel cracks (see fig. 9), which may be afterwards cemented by mineral matter, as we have seen to be the case with the rocks at Point Ælianus. There is also the orientation due to original bedding in the case of the laminated rocks. A very remarkable instance of this may be here mentioned as occurring in a rock at Ty-garw, near Beaumaris (195). Between crossed Nicols, when the crystalline elements are most conspicuous, little or no orientation can be seen, but the rock looks like an ordinary mosaic; but with the parallel light it is seen to be broken up into fragments, which lie rather irregularly in the midst of a cementing material of clear quartz with larger elements, but each fragment is seen to belong to a rock which was originally laminated with exceedingly fine lines of ferruginous dust.

The orientation developed in the fine-grained rocks seldom rises above the quincuncial, the orientating mineral being in every case a green mica, though where this is crowded in bands the orientation becomes practically linear. The rocks which best exhibit this are found in the north-eastern portion of the Western district and the neighbouring locality Mynydd Mechell. In the rock from the latter (212) the direction of the individual crystals follows the banding, as marked by the greater or less abundance of the mica, and the bands follow the contortions. Hence we may assume the orientation to be coincident with the bedding. But in the fine schists found at Caer Ceiliog (9) and Llanddeussant (20) (see fig. 10) it is different. In these, and particularly in the former, certain narrow

bands of dustier material are seen to pass in an undulating manner across the slide, marking the contortions to which the rock has been subjected. But the crystals of green mica have no relation to these lines of bedding, but are arranged somewhat obliquely with reference to a series of parallel cracks, which have produced what is practically a strain-slip cleavage. The direction, therefore, of the orientation is governed by the stresses to which the rocks have been subjected. A somewhat similar phenomenon is seen in a rock at Bodedern (23), only in addition the mica is so crowded in certain bands as to be satiny, and the orientation becomes in part elemental.

An increase in the green mica of such rocks produces very beautiful and characteristic results. In some cases the fine flakes are so crowded, and have an orientation in two directions, that they produce a kind of *felted* structure (see fig. 11). Such a kind of rock is seen below Bodafon Mountain (110), where there is least regularity in the flakes. In the so-called Silurian at Llanfaelog (82), and at Bodlew in the Eastern district (147), one set of flakes pass in one direction, and a smaller set are at right angles to them. But at Trewyn, near Bodafon (104), and at Bodewryd, in the Northern district (220), there is a very close quincuncial orientation, with a laminar orientation of ferruginous dust. These differences doubtless depend on the original material of the rock; but, practically, the metamorphism of these felted rocks and that of the mosaic rocks has gone as far as it can in either case.

We now pass to the chemical alterations effected in rocks of larger elements. Some of these we have already seen to have their matrix pass over into a mosaic, with or without the addition of some green-mica. Others, in which the large elements are more abundant, as that to the west of Llanfechell (219) and near Llanrhwydrus (213), have simply chlorite infused between the fragments; a method of alteration which attains its maximum at Bryn Minceg, near Llandegfan (189). In other cases, as at Ty Croes (85), green mica is the interstitial mineral; and in others, as near Bodafon Farm (106), both are present, particularly in the neighbourhood of some parallel cracks which give a bedded appearance to the rock.

More interesting is the study of the quartzitic rocks, in which alteration would seem harder to induce, and less easy to be made to result in orientation. Yet the greater number of those examined are known to show cleavage on a large scale. Of the ten rocks of this kind examined, three belong to the Bodafon district, two to Holyhead, and five to the South Stack Series. Now, it is known that while the rocks of the two latter localities cleave well, those of the first do not. This difference in behaviour ought to correspond to some difference in structure. A very short examination shows there is a marked difference. In the three Bodafon rocks from Carnedd a Tre'r beidr (107), the summit of the hill (109), and Craig Fryr (110), the orientation is elemental; there is abundant green mica or sericite, but the quartz fragments are themselves elongated, and their junctions have become sutural where they come into contact, and they show further signs of pressure. In contrast to this, the rocks from the other districts have no elemental orientation, and show fewer signs of pressure. The deduction from these facts appears to be that elemental orientation is not favourable to cleavage, and that though cleavage may be produced by pressure, there is a point beyond which, if the pressure be increased, the cleavage is destroyed again.

The cleavage in the Holyhead quartzite (1) is not of the ordinary character, as may be well imagined, seeing that quartzite is not one of the most usually cleaving rocks. It is, however, remarkably orientated with a variety of quincuncial orientation—i.e., instead of isolated crystals being orientated, there are groups of such crystals. These, which are flakes of colourless mica, form a large portion of the rock, and the intervals between them are filled with quartz elements without very clear boundaries. The orientated mica does not in the least turn aside in the neighbourhood of the quartz fragments; on the contrary, the ends go straight against them, and seem to cut into them, so that their boundaries are jagged. In this rock, therefore, the cleavage is the result of the orientation, and there is no deformation of the particles. We must not, therefore, in this case speak of cleavage-foliation, but rather distinguish this—the foliation—as one cause of cleavage, which may be called *foliation-cleavage* (see fig. 12). The quartzites of Roscolyn (65), Porth-y-gwalch (64), and other beds in the neighbourhood (66) are also well cleaved, but the cleavage is brought about in a different way. As before noted, the fragments are smaller, and they fit closer together, so that there is not room for much mica. What mica is present is quincuncially orientated in the usual way, and would scarcely account for the cleavage. The rocks, however, are affected by a number of cracks, and along these the mica is continuous, and it is doubtless along these also that the rock separates, as is the case at Point Ælianus. This is, therefore, a distinct method in which cleavage may be brought about. Such cleavage might be called *fracture-cleavage* (see fig. 9).

In this group there is another remarkable rock, which has been discussed by Sir A. Ramsay—viz., the flaggy bed at the South Stack Lighthouse (60), which seems to show false-bedding, and foliation along the lines of the false-bedding. In the section of this rock the primary bedding is well shown by lines of brown dust, but when the rock is examined with the paraboloid there is nothing seen between these which should indicate false-bedding. There are, however, a number of parallel oblique lines, scarcely definite enough to be called cracks, in which the mica is continuous; but the individual elements are not placed in the direction of these lines, not parallel to the bedding, but in a direction intermediate between these two, so that they overlap like a dislocated pack of cards. It is to these oblique lines that the appearance of false-bedding is due; it is in reality a kind of oblique foliation, whose origin is not very clear. Similar phenomena have been noticed by authors in other districts.

The foliation of the laminated rocks does not require many words of description. In the Western district it is typically quincuncial, but there is a tendency to pass over into the linear, especially as the elements of the green-mica and chlorite are more closely aggregated in the darker bands of lamination, and the orientation of the individual elements is not very closely defined. In the Eastern district it is more entirely linear, the elements of mica being very irregularly arranged and often of large size. In the rock at Porth-yr-cowgl (6) we have the orientation intensified by the pressure which has taken place perpendicular to its direction. In this rock is seen an interesting phenomenon, illustrative of the origin of anthigenetic quartz (see fig. 13). There is a large rounded quartz fragment, caught with its longer axis transverse to the lines of lamination, and therefore more or less in the direction of pressure; one side of this has accordingly broken down, and from the products of fracture there has

been developed a lenticle composed of sutural elements of quartz surrounding the original fragment, and pushing asunder on either side the lines of lamination.

We next come to that large group of rocks which are at the same time crystalline and foliated. Of these we do not actually know the original condition, and it has to be deduced, if possible, from the phenomena of the altered rock. The general composition of these rocks is pretty much the same throughout; the differences are only minor ones. In all there is a large proportion of quartz, while felspar is more abundant in the rocks of the Central district than in those of the Eastern; epidote is an occasional ingredient in the rocks of every district, and mica is found in almost all. These minerals being authigenetic the material from which they have been derived must have been in a different form, and may have been, for all we know, of the same kind as elsewhere forms the slates and grits. The reason that these rocks now differ so greatly from the others must be either that they were different originally, or have been subjected to different processes since their deposition. But they do not differ in the nature of their ingredients, and it can be shown to be probable that they did not differ in the state of its aggregation; in other words, they were probably fine-grained rocks like those which produced the mosaics. In those examples which contain unaltered fragments, the groundmass differs in no respect from those from which fragments are absent; we may therefore restrict ourselves to the former. These fragments are most commonly felspar, a mineral not likely to resist more than others crushing or decomposition. Similar fragments of felspar are met with among the mosaic rocks—in fact they are the last to disappear—while they are very rare among the coarse-grained quartzites. It is probable therefore that the felspar fragments in both cases owe their preservation to their larger size, in which case the matrix must have been of fine material. It may have been laminated, and very probably was. The fine-grained rocks also are more liable to change, as far as the experience of those hitherto examined goes, than the coarse-grained rocks. The conclusion is, that the present size of the crystalline elements is no criterion of the original texture, which was probably fine. Hence the greater crystals must be due to later processes, which have affected these rocks more than the others. Some light may possibly be thrown on the reasons for these differences, by considering the distribution of the rocks with larger and smaller crystals respectively. The elements being throughout of proportionate size, we can judge by the size of the mica. Now the largest mica crystals with linear orientation occur in the neighbourhood of Gaerwen, northward to Penmynydd and southwards to Llangaffo (150, 151, 152, 153, 156, 158), in the Eastern district; also at Porth-y-ly-wod (74) and Gwalchmai Turnpike (71) in the Central district. If we are able at all to tell stratigraphically the centres of change, these would be in their neighbourhood; whereas, when we approach the districts of less altered rocks, as at Bodowyr (146), Bwlch, near Llanddona (209), south of Hafodty (144), Porth-y-fawch (75), and Llangwyfen (77), Mynydd Mechell (211), and the district south of Traeth Dulas (142), we find the mica in smaller elements, and for the most part only quincuncially orientated. This seems to indicate that the greater crystals are due to more intense metamorphism, as we might expect, since the crystals being authigenetic, every large one must have been a small one first. With regard to the other minerals, the present size seems to de-

pend also on the greater or less homogeneity of the material. Thus, in the Eastern district, where the rocks are more thoroughly quartzose, the elements are larger; but in the Central district, where felspar and quartz are about equally abundant, both are of smaller size. In this last case they commonly show laminar orientation, and have a peculiar aspect, like a mass of boiled sago, especially well seen by the use of the paraboloid. Such are the 'grey gneisses' of Gwalchmai (69), Bodwrog (72), Pen-y-carnisiog (73), north of Llangwlllog (78), and south of Holland Arms (154). Why the metamorphism should be greater in one place than another is not easy to say. Certainly in one case there is a neighbouring mass of granite, and in the other a large number of intrusive masses, yet the phenomena have no relation to contact metamorphism. But the presence of these masses, on the one hand, indicates the proximity of heated conditions; and on the other, when pressure was brought to bear upon the rocks, they might act as buttresses. There is no special evidence to connect any of these crystallisations with particular intensities of pressure.

With regard to the orientation of these rocks, we have every kind exemplified amongst them. The quincuncial orientation is, as before stated, best shown when the elements of mica are small. It is beautifully seen in the rock at Porth-y-fawch (75), in which the mica crystals are exceedingly sharp and clean, and two or three of them often stand end to end. At Llangwyfen (77) maxima and minima of mica occur in alternate bands, the former being probably a later product, developed in parallel cracks. The rock at Penlon (142) shows a sago structure in its other elements, and at Mynydd Mechell (211) there are numerous derivative fragments.

The linear orientation is especially characteristic of the Eastern district. It is well seen to the east of Gaerwen (156), where magnificent crystals of mica run in irregular lines, or crowd in bands, the other elements being quite unorientated. In this and two others in the neighbourhood garnets are found, probably as the final result of crystallisation. The rock in Llangaffo cutting (150) is remarkable for the straightness of its mica, and that at Berw Ycha (152), which is full of quartz fragments, shows that, in spite of these, crystallisation of the matrix can be carried to its furthest extent, and linear orientation still be carried out, in remarkable contrast to the quartzite of Holyhead. This is also the character of the orientation in the two rocks of the Central district at Gwalchmai Turnpike (71) and Porth-y-ly-wod (74), already referred to as containing large mica crystals. Both of these, however, are more dusty rocks, the former from the presence of actual dust, the latter containing granular epidote. The laminar orientation of the sago-like grey gneisses of the Central district has already been mentioned. In three of them—viz., at Pen-y-carnisiog (73), Gwalchmai (69), and Bodwrog (72) the orientation is assisted by quincuncial mica; but in that north of Llangwlllog (78) there is very little mica at all.

Elemental orientation, which would seem at first sight to require more pressure, and therefore more metamorphism, does not appear to characterise anywhere the grey gneisses or mica schists, but rather to occur in localities removed from these, where the rocks are generally surrounded by less altered types. The only exceptions to this are at Bodowyr (146) and Hafodty (144), in the Eastern district, and these appear to owe their character to a pressure acting subsequently to their first metamorphism.

The best examples of elemental orientation are seen at Abersant (19), in the Western district—the only locality in that district where coarse mica-schist occurs; also near Bodafon (105) and at Tros-y-gors (155), near Menai Bridge. All these are composed of elements which in an ordinary section polarise in neutral tints, whose long diameters are in general about twice the short ones, and whose boundaries are sutural; the mica is, of course, parallel to these, but varies in amount, most of it occurring at Abersant and least at Tros-y-gors.

Confused orientation is seen in the rocks at Llanflewlin (210), Roscolyn (67), and south of Traeth Dulas (141), only some of the elements being orientated, and all containing numerous original fragments. In these the orientation is also assisted by lines of epidote which, as in the case of the Roscolyn rock, is aggregated along certain lines and produces cleavage. At Y Foel, Llanerchymedd (80) the rock has no crystals of mica, as that mineral has passed over into fine granular sericite, and the principal orientation is due to the other elements.

There are two other crystalline rocks which cannot well be included in any of the above groups; they differ widely from the gneisses, yet have no resemblance to the mosaic rocks. One of these is a highly micaceous rock in the railway between Llanerchymedd and Llangwilog (93), containing both derivative and authigenetic mica, while the quartz and felspar have sutural boundaries. It looks like a peculiarly altered volcanic tuff. The other is from Gorse Mill, Gwyndy (81). It also has large derivative mica, but the authigenetic elements are much decomposed, and only occasionally show elemental orientation.

We have now to consider the alterations of a mechanical nature. It is by no means assumed that mechanical forces have played no part in bringing about the chemical changes already described, but the effects in these cases are not direct. The phenomena now to be dealt with are the immediate results of mechanical forces observable in the rocks as they now are. The results of these forces will be different according to the power of the rock to resist disintegration. If it possesses that power the effects, if any, will be observable in the elements themselves; if not, their relations to each other will be affected.

The effect of pressure on a crystal or an isotropic substance is well known. When an ordinary unpressed crystal is viewed between crossed Nicols it will show a definite colour according to its position relatively to the planes of vibration in the Nicols, and as it is rotated the colour will change equally all over the crystal, and every part in a certain position will extinguish at the same time. When, however, such a crystal has been subjected to pressure sufficiently great to have an effect on its molecular constitution it will show unequal polarisation. Hence the colour of any such crystal will not be the same throughout, but will vary from spot to spot, and when it is rotated different parts will extinguish at different times, and the darkness will pass over it like a wave (see fig. 13). Such an extinction has been called *undulose extinction*. As, however, the corresponding phenomenon is seen without rotating to extinction, and the colours pass over the crystal like a shadow, a more general title to use would be *spectral polarisation*, without any reference to extinction. This phenomenon has also been beautifully referred to as 'strain-shadows.' The mode of description here proposed, however, lends itself more easily to grammatical inflexion. Such a phenomenon, then, may be taken to prove that the crystal has been strained beyond its limit of perfect recovery.

Fig. 14. (157)

Fig. 15. (148)

Fig. 16. (62)

Fig. 17. (193)

Fig. 18. (232)

When, however, a complex of small elements, whether original or produced by the disintegration of a larger crystal under pressure, is similarly affected, the colour of each small element changes towards the edges and thus becomes confused with that of its neighbours. Hence, instead of each element being distinctly marked off, the colour gradually fades on all sides into that of the others, and a general haziness and indefiniteness of the complex mass is the result. This phenomenon is immediately recognised on slightly rotating, or even simply examining a slide affected by it, and it is proposed to refer to it as *microspectral polarisation* (see fig. 14). It is the most faithful indication of the previous stress the rock has been subject to. It is sometimes referred to as a quartz-felspar mosaic, but it differs essentially from such a mosaic as is produced by the growth of small definite crystals, and should not therefore be designated by the same word. Numerous instances of this occur in the rocks already referred to. Thus the quartzites of Bodafon (109) and the cleaved rocks of Roscolyn (66, 67) show it in a high degree, while the cases in which individual crystals show ordinary spectral polarisation are too numerous to mention.

The two cases, however, must be distinguished in which, on the one hand, a complex of small elements is the primary subject of pressure, and, on the other, when the pseudo-elements are the results of the disruption of a larger one. In the latter case the boundaries are much more indefinite. In the cases above referred to the elements were originally small; and of this kind another example may be quoted—viz., the rock near the river Cefni (102), which has a slaty aspect on the large scale, in which not only the quartzose or felspathic elements are affected, but also the abundant mica which had previously filled the cracks. In an example, however, from Bodlew (148) both varieties are seen side by side. In this the original small elements produced by primary metamorphism are indicated by fine interstitial flakes of mica, while in the midst is an infiltrated quartz vein which is broken up into optical elements, so that the greater indefiniteness in the latter case can be easily appreciated. When such a rock is examined with the paraboloid, the elements which have thus optically broken up are seen to possess a peculiar structure. They are affected by a number of curved or crinkly cracks, like the surface of crape, which are sometimes parallel throughout the original element, and sometimes radiate from the apex of an adjoining crystal. In the rock at Bodlew they are seen to occupy the intervals between the broken fragments of a large microcline crystal, and cannot therefore be in anything but vein-stuff. These cracks are very minute, about $\cdot 0005$ inch apart, and can only be seen with the paraboloid. Such a structure may be called *crape structure* (see fig. 15). It is necessarily accompanied by microspectral polarisation, but the converse of this does not hold. In the case above quoted both the original small elements and the later vein are microspectrally polarised; but in another case in which the elements of primary metamorphism are larger—e.g., at Ty Mawr, Llandaniel (149)—they are unaffected, while the interstitial segregation quartz shows the crape structure. This would seem to suggest that the elements of primary metamorphism were formed under so great a pressure that the later pressure, producing the new phenomena, did not reach their limit of elasticity, and consequently they were unaffected. If this be the case, since small elements are affected they must have been produced under less pressure.

Besides those already quoted there are admirable examples of this structure in the boss of rock in the field on the east of Gaerwen Windmill (158), and at the northern extremity of the mass marked 'gneiss' on the survey map (160); in both cases all regularity of structure on the large scale has been destroyed. The rock at Y-graig (159), near Gaerwen, seems to have been subjected to still greater pressure, since, accompanying an unusual amount of spectral polarisation in the elements, the structure is commencing to show itself on their edges, which break up into optical fragments. A similar explanation applies to a fine-grained rock at Gors Llwyd, Llaniestyn (161), the edges of whose elements are optically very intricate indeed.

The results of pressure which affect the relations of elements between themselves are various. The simplest is the production of ordinary cracks, which in no way interfere with the remainder of the rock but are filled with new elements, usually of quartz of larger size, but occasionally of felspar, as in the gneiss of Gwalchmai (69). In some cases in the Western district these cracks are filled with a complex group of quartz and green mica crystals, the latter arranged quincuncially, so that the result is very like a fine schist, and in fact illustrates the formation of such, and may be taken for it in fragments as at Llanfechell. There are very few rocks in the whole sedimentary series which are not affected by later cracks, often of two or even more periods of formation, but they do not materially alter the character of the rock. Particular instances, however, have already been noticed in which such cracks are numerous and parallel, and are filled with some flaky mineral, and in these cases they give a banded appearance to the whole mass, and cause it to split or cleave into fairly thin plates. In the fine-grained rock at Caer Ceiliog (9) and others it has also been noticed that the minute flakes of green mica are arranged obliquely in reference to a series of small parallel cracks transverse to the original bedding. The most remarkable example, however, of this strain, produced on the neighbouring material by the formation of cracks, is seen in a rock from the South Stack Series at Porth-y-crug (62) (see fig. 16). The section contains part of the gritty filling of a worm-track, as it seems, in the midst of very fine detritus which has now become silky with the numerous sericite flakes. Possibly this tube of grit has formed a buttress in the movement of the rock, for now the remainder is broken up into a series of cracks, associated in parallel groups, which have had the effect of contorting the fibres into beautiful sigmoid folds, which often now run perpendicular to their original direction. It is a sort of 'strain-slip cleavage' on a small scale. The whole phenomenon dies away at a little distance from the tube.

When the fracture of the rock is carried further, the original structure may be quite obscured, all regularity may be lost, and the bulk of the material may be the infilling of the cracks. Such results are by no means uncommon, and, indeed, most of the rocks which do not reveal their nature by a microscopic examination owe their peculiarities to the fracturing they have undergone. The most instructive examples, however, of this structure are met with in the Eastern and Central districts, where the general metamorphism has been the greatest. Thus the rock at Minffordd waste (162), which weathers into pencil-shaped pieces, is more than half occupied by an infilling of chlorite—the fragments being of a coarsely crystalline irregular aggregate. So in the rock at Gallows Point, Beaumaris (197) there is so much quartzose calcitic

vein stuff that the original fine-grained chloritic material itself looks like a vein in the rest. Again, the rock at Bryn Gorsddu, near Newborough (143), was once one of the ordinary coarse mica schists; but now the intervals between the fragments into which it has been broken are filled with a new and abundant growth of secondary mica, which gives the characteristic appearance to hand specimens. In the railway cutting south of Holland Arms (151) one of the rocks has patches of larger elements of quartz and mica confusedly mixed with smaller elements. Naturally, micro-spectral polarisation is common in such rocks, and in some cases is better shown than in the less fractured ones. For instance, at Cefn Du, Gaerwen (157), in the segregation veins of quartz, this and the crape structure are a perfect picture (see fig. 14). In another case in this district, between Garth Ferry and Beaumaris (194), the bulk of the rock is a mosaic of fair-sized elements, but the whole is utterly broken up and irregular; yet there is orientation produced by the various materials that time after time have filled up the cracks. In the Central district such broken rocks occur near a line along which, on stratigraphical grounds, a fault is believed to run—*i.e.*, at Porth-y-ly-wod (84), west of Gwalchmai (70), at Ynys Coed, Coedana (135), and in the area north of Llangwilog (79). These are all broken up grey gneisses. The rock at Ynys Coed, Coedana, is particularly instructive, as, the cracks being filled with abundance of chlorite, it has been taken for a 'greenstone.' There is also another rock in this neighbourhood, north of Llangwilog, which has been called a hälleflinta (87), which is so utterly broken up and recemented that its origin is quite doubtful. Other rocks of an entirely confused nature, owing to dislocation and infiltration, have been observed near Bodorgan (88) and Llangefni (101). In the former of these, the shifting is made plain by the dislocations of a small vein which crosses several elements of quartz. The whole of these rocks, though not originating as holocrystalline ones, may be referred to as cataclastic, since they have undergone the same disintegrating mechanical processes as those which are so called.

A more important effect of pressure, because more widely developed and of more theoretical interest, is the production of mylonitic lines. These are peculiar features characteristic of the rocks which have been called Mylonites by Professor Lapworth. The most typical of these mylonites occupy the position of the thrust planes which divide up the rocks in the north-west Highlands. An examination of one of these from the Erribol district will give us the characters of such rocks. We find in it abundant micro-spectral polarisation, as we should expect, but it also contains, in the midst of crystalline matter, a number of lines, which are remarkable for their continuity, and often for their tenuity, and which part asunder on reaching a fragment, to curve round again into contact when the fragment is passed. Many of them are composed of opaque white dust, whose particles are indistinguishably small; but many others are converted into sericite, which, when it terminates, is frayed out into indefinitely fine ends, like cirrus clouds. These are the mylonitic lines. In the case quoted, their production has been accompanied by motion of the rock in their direction, combined with great pressure perpendicular to that direction—in other words, they have been produced by shearing. The converse of this may be safely assumed, and when stratigraphical evidence of shearing is absent, these lines in a rock may be taken to prove that it has been subjected to such a stress. Such

lines are admirably shown in many of the Anglesey rocks. In some they occur as simple lines of dust, which may give a pseudo-laminated, or slaty aspect to the rock, as at Porth Dryw (12). A more remarkable example is in the north-east of Malldraeth Marsh (190). The rock has all the aspect of a purple slate, and, indeed, both it and the rock at Porth Dryw may never have been anything else. But at present the mylonitic lines obscure all other features, the whole rock being mylonised, and the intervening substance, though very minute, is microspectrally polarised. In the rock at Pen-y-Parc, Beaumaris (193), they have to pass round the numerous small fragments of quartz, which they do in a characteristic way, and they are largely converted into frayed-out sericite (see fig. 17). In the rock at Tyddyn, north of Beaumaris (199), they are so abundant that with the frayed-out sericite they occupy broad bands, leaving only small intervening portions, in which microspectral polarisation may be observed. In most of these cases special causes may be suggested that should cause shearing in these localities. In other cases the lines are now entirely crystalline, but can still be recognised by their other characteristics, and by the fraying out of the ends of the sericite. In this state they are well seen in the slaty-looking rock at Porth-da-farch, Holyhead (61), at Clawd-y-parc, Llandegfan (196), at Coedmawr, Llanfaes (200), and at Llechog Ucha, Amlwch (221). In some cases the lines are so abundant and regular that they may probably coincide with the original lines of lamination, which have been drawn out in their own direction, as beyond Porth Dryw (13), and at Pont Scyphydd, Llanddeussant (25).

ROCKS OF SPECIAL ORIGIN.

Amongst the ordinary sedimentary rocks of Anglesey are found certain special types which differ from the rest both in their mineralogical composition and in their mode of occurrence. These are found in isolated masses, often of peculiar form, and are quite characteristic of the series to which they belong. Their origin must be partly determined by their stratigraphy, but their microscopic structure may throw some light upon the question. The two principal types are limestone and quartz rocks.

Limestones.—These are of several types, some of which have been already described by Professor Bonney.

One form of limestone, which occurs, like all the rest, in isolated or lenticular patches, is found amongst the crystalline rocks of the Central district, and partakes of their character. Since the rocks amongst which they are found have been recrystallised, these have doubtless been also, especially as they are distinguished from the rest by the large size of their elements, which vary from .02 to .04 inch in diameter. The crystals are characteristically twinned, and occupy the mass of the rock, with only a few grains of quartz, mica, or black dust in the interstices. The one at Trecastle (90), discovered by Dr. Callaway, is orientated with the rest of the schists, but that at Bodwrog (91), inserted on the Survey maps, is disturbed and irregular. These were, doubtless, like the other varieties before their recrystallisation, and may be considered to have had a similar origin. There are limestones also in the older or more stratified portion of the series in the Western district. One at Porth Delise (15) occurs in an irregular tongue in a disturbed area, and is doubtless out of its original place. Its later alteration is well marked by the abundance of large crystals of mica associated with the calcite; another at Crugas,

Fig. 19. (217)

Fig. 23. (50)

Fig. 24. (165)

and a third at Ceryg Moelion, are closely associated with the serpentine of that area, and will be described in connection with the latter. The one at Ceryg Moelion has been considered by Professor Bonney to be an infiltration from carboniferous limestone which may once have overspread the district.

Another type occurs amongst the unstratified materials, either where the rocks are fine-grained, or where they are obviously volcanic accumulations. These are generally formed of small isodiametric crystals, without twinning, which form a mosaic, and only contain the large twinned crystals in later cracks. They are exceedingly pure, and show no signs whatever of pressure, and occurring as they do in lenticular patches it is impossible to believe that they are parts of bedded rocks brought into their present position by folding; they must, on the contrary, have crystallised *in situ*. Those with the largest crystals, about .002 inch diameter, occur where the rocks are most altered, as behind the Druid Inn on the old Holyhead Road (92) in the Central, and at Rhyd Eilian (202) in the Eastern, district. A similar rock has been described by Professor Bonney from Wugan, Pentreath. Where the rocks are of finer grain, as at Llanfaethlu (26), the calcitic, or perhaps dolomitic, elements are smaller; but the smallest of all, being not more than .0002 inch diameter, are found in the limestone at Llanlliana (218), where the rock is on a larger scale, and is more or less stratified. In those masses which are found amidst volcanic accumulations, and whose mode of occurrence is similar to that of an intrusive rock, there is generally some admixture of quartz. Thus at Port Unal, on the Northern coast (215), the general elements are small dolomitic (?) ones, but the shrinkage cracks are filled with quartz; and at Careg Gwladys (205) quartz occupies narrow interstices between the calcareous elements, as well as the cracks, and sometimes increases so much as to form the greater part of the rock.

Another remarkable type, but of somewhat similar mode of occurrence, is the oolitic rock of Llanbadrig (217) (see fig. 19). The original basis of this is a crystalline mass of small elements with shrinkage areas of larger ones, and is therefore identical with the Llanfaethlu limestone. But this original mass has been broken up into fragments, each fragment has been coated with a band of calcitic dust, and then these dust-coated fragments are enclosed in a similar matrix to the original. Two or three thus imbedded go to form a larger fragment, and this again is coated with another layer of calcitic dust, or a second coat may be deposited on an original fragment, and this process goes on again and again; and, lastly, the interstices between the final fragments have been filled up with calcite in larger elements. We can thus trace the gradual building up of the rock *in situ*, and can recognise that the process is exactly what might take place in the action of a calcareous spring, producing a chemical deposit.

Certain limestones in the series have a more bedded aspect in the field, and these are found to differ fundamentally in their structure from the above. Thus another rock at Careg Gwladys (204), which looks more coarsely crystalline, has a number of large, well-formed rhombohedral crystals of dolomite, either isolated or in groups, imbedded in a matrix of quartzose fragments interspersed with a brownish opaque dust. The edges of the dolomite crystals generally have a band of clearer crystalline matter, but they are often broken and irregular. Such a

structure seems to indicate a sedimentary rock whose materials were obtained from other deposits in the neighbourhood. The rock at Cerrig Ceinwen (94) consists of a mixture of fragments of calcite and jasper, re-cemented in a mass of calcite. These fragments are irregular and unworn, so that, whatever was their first origin, they have been broken up *in situ*—i.e., the rock is cataclastic. Its structure is beautifully shown by the paraboloid.

With these limestones may be included certain rocks which owe their origin to an infiltration of calcareous matter into rocks already formed. A very considerable number of the ordinary rocks have a certain amount of calcite in veins, proving the presence of such material in the infiltrating water; but only in two cases amongst the rocks observed has this gone so far as to make the calcitic element predominate. One of these occurs in the laminated schists at Porth-y-defaid (16), and gradually passes into the ordinary rock in the direction of the laminæ. The groundmass is quartz in large elements, and the calcite is imperfectly crystallised in minute particles which aggregate together in irregular areas. There is also here a quantity of chalcopryrite, which decomposes into a homogeneous transparent substance with the colour of malachite. The other is in the fine-grained rocks at Chlorach Bach, near Llanerchymedd (103), where a quantity of calcareous matter without crystalline form is mixed up uniformly with a mass of minute elements of quartz and sericite. It differs only from the other rocks of the neighbourhood by the abundance of the calcareous matter.

Quartz Knobs.—The rocks to be described under this head all occur as isolated knobs of greater or less size, surrounded on all sides by shales or schists, in whose orientation they take no part and produce no interference. They have, in fact, no orientation, either on the large or on the microscopic scale, and they show no signs of contortion. Hence their stratigraphical relations in no way suggest, but, on the contrary, strongly oppose, the idea of their being brought into their present position by the folding of any bed. They occur in various places and in various relations, yet they have always approximately the same form. These facts must be borne in mind when we attempt to interpret their structure. They are for the most part entirely composed of quartz; only one or two, which must be referred to the same group, contain a trace of other minerals. By this character they are completely cut off from all the other rocks of Anglesey—even the whitest quartzite in a bedded form, such as that at Porth-y-gwalch, being much less pure. We may consider, first, those in which no certainly derivative elements can be recognised; and then those in which they are certainly present.

Of the first group the foremost place must be given to the great knob to the south-west of the Parys Mountain (232) (see fig. 18). This is for the most part composed of large quartz elements, comparable with those of a granite, which from their intimate sutural boundaries may be certainly judged to be authigenetic. These are dotted over with very minute white specks, which are almost absent from their boundaries, so that, as seen with the paraboloid, the rock is divided into a number of closely-fitting polygons. This *polygonal* structure, which is very characteristic of these quartz knobs, is to be seen also in many of the veins and patches of secondary quartz in the ordinary sedimentary rocks, and hence may be taken to be an additional evidence of authigenesis.

There are also occasional irregular patches of smaller elements. In

no case in this rock is there the slightest evidence of anything between one element and another, nor of the presence of any other mineral than quartz. When seen on the large scale there are appearances of a previous fine banding in some parts of the rock, and of these being subsequently broken up, and recemented by fresh quartz. One such band is recognisable in the slide. It is composed of rather clearer elements, followed by a crack, on the other side of which the elements are smaller. This crack is thrown into such deep sigmoid folds that, if ever it was straight, the rock must have been greatly compressed; yet the only sign of pressure is a slight amount of spectral polarisation. The rock is also traversed by veins, in which the elements are clear, but are nevertheless in optical continuity with the previously-formed elements on either side. These veins were subsequent to the folding of the crack, as the crests of the sigmoids are cut off by them. The rock has, therefore, had a long history, and the earliest form traceable is the polygonal structure. If now we compare this with the structure of a jasper, such as is associated with the limestone at Cerrig Ceinwen (95), we find in the latter also the whole mass, with the exception of the fine ferric dust, to be siliceous and mostly quartz, but the elements are small and irregular, though with sutural boundaries. In this case we are sure that the rock has been produced directly from siliceous waters, and the chief difference between the two is in the size of the elements. There is just the same difference between the elements of a granite and a felsite of the same composition. It is possible, therefore, that there may be the same relation between the quartz rock and the jasper as between these two. In other words, the quartz rock was more slowly formed, and at greater depths beneath the surface. From these considerations, from the banding of portions of the rock, from its purity, and from the mode of its occurrence it has been suggested that such a knob represents the underground base of a hot spring of the period.

If this is the most satisfactory explanation of this particular rock it must be allowed to have its weight in the interpretation of the others, which resemble it in mode of occurrence, but which present greater difficulties. The purest of these occur also in the Northern district, and have been examined from Bull Bay (231), Port Unal (214), and Pen-bryn-yr-Eglwys (36). In these the elements are not so uniformly large, though the larger ones have equally sutural boundaries and polygonal outlines; but there is also a considerable quantity of finer elements irregularly dispersed, and some of them have a minute sericitic boundary. There are, moreover, in the two first some rare and minute zircons, and in the last some certainly derived fragments which are not of quartz. Still the rocks are essentially pure quartz, of which by far the greater part is certainly authigenetic. Although it is difficult to account for so great purity in a sedimentary rock, like an ordinary quartzite, it is not difficult to account for the slight impurities that might be present in the deposit from a siliceous spring.

In the case of the other quartz knobs which have more numerous derived fragments, these still have a special character, though, no doubt, if it were not for the peculiar stratigraphy, and the existence of purer quartz rocks having the same form, some of these might well pass for grits. If we examine the quartz rock of Bethel, Bodorgan (96), we find that the most conspicuous of the derivative elements are quite peculiar. They are larger than all the rest, and their outlines are very rounded, and they

have a layer of sericite clinging closely to their surface. At the same time they are clearer, the specks in them are not scattered irregularly, or absent from an external band, but lie in different planes produced by cracks which go across from side to side and intersect each other; many of them are also crowded with fine crystalline needles. These rounded grains are not at all like any of the fragments in the ordinary quartzites, nor like any authigenetic element in the schists, more especially in the particular of the fine needles—these point to a source such as that which produces granitic rocks. In any case these rounded derivatives are sharply marked off by all their characters from the remainder of the rock, which consists of polygonal authigenetic elements of almost complete purity, with the exception of a little sericite. The rock thus contrasts strongly with any of the bedded quartzites, notwithstanding that it is quite small in bulk, and surrounded by slaty rocks, and the peculiar roundness of the derivatives presumes a long attrition. Have these been worn by the very water from which the matrix has derived its silica? and has the attrition taken place, not in streams on the surface, but in circulating currents underground?

From this we may pass to the knob of quartz at Pen-y-Parc, Beaumaris (203), described by Professor Bonney. In this the derivatives are very numerous, and not all of quartz; yet is the general character of the rock the same, and it has the characteristic mode of occurrence, and it is impossible to imagine it brought into its present place by folding. In fact, though the neighbouring rocks have been shown to be crowded with mylonitic lines, no spectral polarisation affects the quartz. On the contrary, one of the derivatives shows microspectral polarisation developed before its deposit, and not continued into the surrounding matrix. Notwithstanding, therefore, its great similarity, in many respects, to an ordinary quartzite, we may conclude that the circumstances of its origin were different, and the general method of production the same as in the other quartz knobs.

There are many other similar quartz knobs in the island, which have not been examined, but the great mass at Llangefni (97), marked 'greenstone' on the Survey map, is peculiar. It is much larger than any other, and from a distance looks to have almost a bedded appearance. There are a great many derivative fragments in it, but in the character of these and of the matrix it much more closely resembles those above described than any of the ordinary quartzites.

Green Rocks.—Besides the limestones and quartz rocks, there occur occasionally, in similar isolated masses which often weather into knobs, certain green rocks which show no structure on the large scale but look minutely granular. These are found to be composed of minute crystals of definite minerals, which seem to have segregated in such separate masses. Some, as at Borthwen, near Roscolyn (68), are composed of epidote, whose crystals are separated by lines of black dust, and with shrinkage areas filled with quartz. Others, as at Porth Delise (14), which are more fibrous-looking, are composed of a greenish transparent mineral arranged in tufts, which polarise with a grey-tint like serpentine, of which they are probably a variety. In another, south of Beaumaris (192), the nature of the principal dusty mineral without any form is obscure, and may be decomposed epidote; the green colour is produced by the ground-mass of chlorite. These masses are mostly confined to the most altered rocks, and seem, like the others of this group, to have a chemical aqueous origin.

CRYSTALLINE ROCKS WITH THE HABIT OF IGNEOUS ROCKS.

The nature and origin of the rocks of this group have been and still are the subject of much difference of opinion. Those in which no foliation is perceptible are considered granites and diorites by some, while others have noted in them peculiarities which have suggested that they are extremely altered sedimentary rocks, and have made comparisons between them and the Laurentian gneiss. Those in which schistosity is manifest have been generally taken to be of sedimentary origin; but recently it has been shown that similar structures may characterise igneous rocks under suitable circumstances.

The solution of these questions will not depend on the microscope alone, and the writer has shown what he believes to be satisfactory evidence of intrusion, and therefore of igneous origin, in both cases. However, the present business is to examine their structure, that any conclusions which may be come to may be in the light of our knowledge of this. One thing is certain, that if they be altered rocks we have no knowledge of any unaltered representatives of them in Anglesey, and can only study them as they are. It is, however, for convenience, and not with the intention of begging the question, that in their description they will be referred to as granites, felsites, diorites, &c. Many of these rocks have undergone much alteration, even after they were crystalline as we now find them; but in this case the alterations are so dependent on the original rock that they cannot be considered separately, but we can only consider—(1) their component minerals; (2) their structure, original and induced.

Minerals of the Rocks of Igneous Habit.—*Quartz* is far less abundant than in the rocks of sedimentary origin. In one large subdivision it is absent from the original rock, and occurs only in veins or bands in which it has segregated. Even in the other subdivision it never forms the greater part of the rock, and is more common as the latest-formed mineral in the intervals between the others than as one of primary consolidation and of large size. This is a common feature of the quartz of igneous rocks; on the other hand, considering the exceedingly quartzose character of the undoubtedly sedimentary series, it would be rather strange, though not beyond the bounds of possibility, that a more basic group should have succeeded them in the same neighbourhood.

Felspar.—In the absence of the characteristic banding of plagioclase, and in the presence of abundance of saussuritic decomposition, it is not always possible to determine the species, especially when there are no crystal outlines or cleavages. Doubtless much is orthoclase, but plagioclastic species must be at least equally abundant. With regard to the banding, nearly the same may be said as with regard to the fragments, &c., in the sedimentary rocks. Perfectly regular banding, certainly representing twinning on the albite plan, is very common, but the lines often die out in the midst of the crystal. There are seen also in the coarser granites the finer cross lines, which represent the pericline twinning. The appearances referred to microcline are more abundant in these rocks, and are sometimes beautifully shown, as in the granite at Ynys Dodyn (118). They have all the characteristic indefiniteness and changeability as the slide is rotated, and are also seen cutting at oblique angles down to 60°, probably owing to the obliquity of the section. It is suggestive of these bands being developed by pressure that they are found chiefly in

rocks which for other reasons are known to have been subjected to such pressure, as in the neighbourhood of Llanfaelog and Gwalchmai. Some feldspars also show a broad obscure banding, independent of all the above, which probably represents an imperfect zonal structure.

Mica is not abundant in this group of rocks, except in isolated examples, and in the more basic group it is generally entirely absent. Perhaps muscovite is the most generally diffused species; but whereas ordinary biotite is entirely absent from the sedimentary series, it is here nearly as abundant as any other, to judge by the darker colour and dichroism. It is especially characteristic of the cleanest granites, but is most abundant where the rock is foliated at the margins of the granite areas, as at Tafarn-y-botel (123) and Ty Newydd (245), and in the district north-east of Parys Mountain (251).

Hornblende may be considered the characteristic mineral of the rocks of igneous habit, inasmuch as it never occurs in the sedimentary rocks of Anglesey, either as a derivative or authigenetic. A large number, however, of these igneous rocks contain it as an essential ingredient, always in the common green form. It is entirely absent from the rocks of the Northern district, but occurs in the district east of Parys Mountain. In the Western district it is found only at Pen-bryn-yr-Eglwys, and at Llyn Trefwll, in both cases in association with granitic rocks. The principal localities, however, are in the Central and Eastern districts, where it sometimes forms the greater part of the rock, as near Holland Arms (181).

Glaucophane.—The occurrence of this mineral in the Anglesey schists has recently been recorded by the writer ('Geol. Mag.' N.S. Dec. III. vol. v. p. 125). It is there stated to occur in long narrow prisms with incomplete terminations, which have a rhombic cross section with an angle of about 124° , sometimes modified by the clinopinakoid. The extinction, as far as can be determined, makes an angle of about 15° with the length of the prism, which is somewhat greater than the characteristic amount, and approaches the angle of hornblende. Hence Italians would call the mineral 'gastaldite.' The characteristic blue colour is seen when the length of the prism coincides with the short axis of the polariser, and it has a violet tint when placed in the perpendicular direction. In the rhombic section it has a slightly yellowish tint. The crystals are usually interfelted, so as to have no definite boundaries, but they are occasionally seen floating separately in the layers of quartz which sometimes penetrate the rock. This mineral has only been hitherto found in one very schistose group of rocks in the Eastern district, and even there it passes locally into hornblende and decomposes into chlorite. It is best seen in the rock near Anglesey monument (168, 169). For a figure of this rock see Teall's 'British Petrography,' plate 37.

Epidote is perhaps the most widely distributed of all the minerals in these rocks, though from its small comparative amount in each the aggregate is not so great as of others. It usually occurs in isodiametric elements, often with crystal outlines, and occasionally lath-shaped and radiating. It also occurs in long pulled-out bands in rocks which have been dynamically metamorphosed. It is most abundant in the gabbro schists of the Western district, in the diorites of the Central district, and in the hornblende and glaucophane schists of the Eastern district. In many cases there is no direct evidence of its being a secondary product; and in one case, that of a spheroidal rock, near Amlwch (227), it appears to have developed out of felspathic groundmass, without actual feldspar preceding it.

Chlorite is equally abundant as a decomposition product in the igneous as in the sedimentary rocks. It is formed from either hornblende, epidote, or mica. It shows feeble polarisation, and therefore is not the green-mica of the sedimentary rocks.

Sericite is also common as a result of the decomposition of white mica, or as an infilling of the interstices between other minerals.

Sphene is an abundant and characteristic element in the hornblendic rocks of the Central district, especially in one at Craig-yr-allor (131). The crystals are never perfect, but their brownish tint, high refractive index, characteristic cleavages, and weak double refraction are quite distinctive. It occurs in the midst of felspars or other minerals in irregular grains, which are often worn so as to look as if they belonged to a previous generation. It is sometimes associated with ilmenite in such a way as to suggest its derivation from that mineral, as has been shown to be the case in some American rocks.

Ilmenite and Leucoxene.—The presence of one or other of these depends on the state of decomposition only, so that the presence of the latter indicates the original presence of the other. The dark black substance which is associated either with leucoxene or sphene is taken to be ilmenite. It occurs in abundance in the hornblendic rocks of the Central and Western districts, and also in the finer-grained granites. The leucoxene is often in skeleton crystals, only partially presenting hexagonal outlines. It is best seen in the diabase between Amlwch and Parys Mountain (229).

Rutile is not a common mineral here. It occurs as isolated crystals of prismatic form in some of the hornblendic rocks of the Central district, as at Plas Llanfihangel (136), and also in much smaller grains in some of the finer rocks of the same kind at Gaerwen (177).

Apatite is an abundant mineral in the hornblendic rocks. In mode of occurrence it agrees entirely with the sphenes, and is seen side by side with them in the rocks at Penterfyn (134). Like that mineral its refractive index is high, but not so high, and it is remarkable for its beautiful clearness. It often occurs in characteristic hexagonal prisms. There are many occurrences, however, of irregular masses, which by all other characters must be assigned to the same mineral. Apatite also occurs in needle-like prisms in several of the felspars and quartzes of the granites.

Garnets are numerous in certain of the rocks, especially in the volcanic group north-east of Parys Mountain, both in the crystalline and the associated tuffs. But they are very peculiar in their characters. They seldom even make an approach to a crystalline form, but sometimes they are round and sometimes they spread out in a kind of ophitic sheet, without regular boundaries. Moreover, there is often very little garnet left in them. In the first place they contain many inclusions, mostly of quartz, but sometimes of sphene or apatite. Then the actual garnet has been cracked in many directions, and along these lines runs a band of ferric dust, bounded on either side by sericite, occupying, on the whole, a considerable portion of the mineral. The intervening fragments have mostly turned to chlorite, and there is only left here and there a few small pieces, which prove to be isotropic and highly refracting, to represent the original material, and even these are often broken out in the cutting of the slide.

Zircon seems rare in these rocks, unless it has sometimes been mis-

taken for sphene. When the crystals are small they are not always easily distinguished. But in the granitic rocks of Tafarn-y-botel (123) and to the south there are highly refracting and doubly refracting crystals, which are clearer in colour and more vivid between crossed Nicols, which almost certainly belong to this species. It is usually associated with quartz, but not always.

Augite is essentially the mineral of the dykes and minor igneous sheets in this region. Such masses occur amongst the grey gneisses of Llangwfen (125), at the boundary of the chloritic schists of Llyn Trefwll (56, 57), in the boss between Amlwch and Parys Mountain (229), and amongst the volcanic group north-east of Parys Mountain (243). It is generally of the colourless variety, and is well characterised by its cleavage and optical properties.

Olivine in a fairly fresh state occurs in diabases south of Bodowen (127), which stratigraphical and other considerations would assign to part of the volcanic group in the older series.

Diallage is equally characteristic of the gabbro area near Four Mile Bridge and on Holyhead Island, where its well-marked cleavage leaves no doubt of its identification. It has not been found elsewhere. No unaltered olivine has yet been found in association with these rocks.

Enstatite occurs in at least one of the better preserved rocks of the gabbro area—viz., at Ty Newydd (45). It is distinguished from the ordinary pyroxenes by extinguishing parallel to the traces of the cleavage planes. It may be more common amongst these rocks, but not many suitable slides have been examined.

Chrysolite occurs in veins in the gabbro area in the midst of that rock and of the serpentine at the inlet on Holyhead Island, south of the Four Mile Bridge. It is well characterised by its fibrous structure and low polarising tints.

Serpentine, of course, forms the bulk of the rocks in the serpentine area of the Western district, and is not always developed as a pseudomorph of any particular mineral, but occurs also in veins and cracks traversing calcareous and other rocks.

Talc is considered by Professor Bonney to be the mineral which produces the rock quarried as 'soapstone.' It is found at Pwll Clai (54).

Pyrites is a rare mineral in these rocks, but occurs as isolated crystals in a few of the granitic rocks and in the pyroxenic rocks of the volcanic group N.E. of Parys Mountain.

Hematite also occurs in minute brilliantly scarlet crystals, sometimes of hexagonal outline, in the granites of Pen-bryn-yr-Eglwys.

Magnetite may be the black mineral in undistinguishable grains which makes up the groundmass of a rock at Gwalchmai (138), and it is also dispersed throughout the serpentines.

Calcite occurs in many of the rocks in such abundance as to form an essential ingredient. In some cases it is undoubtedly a filtration-product, as at Nebo (248).

Tourmaline.—A few narrow purplish blue crystals, which extinguish parallel to their length without the analyser and look hexagonal, may belong to this species, though the crystals are very small. They occur, where we might expect them, at the edge of the granite mass where it is intrusive into micaceous schists at Maengwyn (122), and also in a quartz segregation area in the glaucophane schist near Castellor (171).

Structure of the Rocks of Igneous Habit.—The rocks now to be described

may be conveniently divided into five groups:—1. The granitic rocks and their associates. 2. The volcanic group east of Parys Mountain. 3. The dioritic rocks and their allies. 4. The gabbros and serpentines. 5. The isolated masses and dykes.

1. *The Granitic Rocks and their Associates.*—These rocks are immediately distinguished from the sedimentary rocks of similar composition—i.e., the mica schists and gneisses—by the largeness of their elements. They seem indeed quite another order of rock; instead of the numerous minute elements of the schists, a single crystal of felspar will often occupy more than the whole field of view, and though the rock is holocrystalline there are none of the sutural junctions so characteristic of the schists. The only orientation in any of them is a very rough linear one, not observable under the microscope. If the larger size of the resulting elements is taken to indicate a greater intensity of metamorphism, then these granites must have been subjected to such influences to a point far beyond the gneisses. The orientation of the latter indicates that the forces they were subject to were ‘directed,’ but its absence in the granites indicates agencies without direction. These conditions are satisfied only by the production of a mobile magma. In other words, the rocks must have been melted. The only evidence of any previous state consists in the occurrence of such minerals as quartz, mica, and felspar as enclosures in the various elements which now form the rock.

The largest mass of granite occurs in the Central district, where it shows several types. We may divide them roughly into those in which quartz is a considerable element, and those in which there is little or none. Of the first of these divisions the freshest examined is that at Henblas, Llandrygarn (117). In this the felspar elements are very large, and the greater proportion are plagioclase. They are very dusty, and in some cases are so much altered as never to completely extinguish; in other cases they are scarcely altered at all. There are some brown mica elements, whose position and relations indicate that they are of the same order of consolidation as the felspar. The quartz is more continuous, and encloses areas of felspar, so that it plays the rôle of groundmass, though some of its elements are large. Fresh, however, as the rock appears, it has abundant signs of having been submitted to pressure since its consolidation. The quartz often breaks up into smaller elements, showing an imperfect microspectral polarisation; the larger elements polarise spectrally, and the appearances of microcline are seen in some of the felspars. If this rock be compared with the granite of Killiney, the resemblance is remarkable. The latter is certainly fresher, but it has the same relations of the elements, and shows also spectral polarisation and microcline structure, but the quartz is not so broken up into smaller elements. On the whole, it appears to only require subjection to a little more pressure to become identical. The best preserved granites at Llanfaelog (112) and Craig-yr-allor (116) are practically the same rocks, and in some parts of the former the quartz is unbroken, and the resemblance of these parts to the Killiney granite is almost complete. On the whole, however, the quartz has been broken by cracks, and these have become broadened and filled with mica, now passed over into chlorite, so that the aspect of the ultimate product is very different from the original. The great majority of the granites examined, however, are thoroughly cataclastic rocks—as, for example, the tongue of that rock at Porth-y-ly-wod (113), at Gwalchmai (115), at Bryn Twrog further north (120) and at Ynys Coed, Coedana (121).

These rocks are shivered into fragments, and the larger are re-cemented amongst the smaller, presenting a true mortar-structure. It is often difficult to recognise the identity of such rocks with a fresher granite, and it is only in the larger pieces which have escaped disintegration that the original character can be seen. It is important to examine the structure of the granite where it is so clearly intrusive in its mode of occurrence at Maengwyn (122). Here it is coarse-grained like the rest, and the feldspars are broken and the quartzes microspectral, and there are a few tourmaline crystals, but it is of the same general type as the rest. The surrounding rock, with which it has an irregular boundary, is a dusty schist, whose small elements have partially crystallised, and which contains large flakes of white mica which have been developed in relation to cracks.

The remarkable foliated rock at Tafarn-y-botel (123), which has so much the aspect of a Highland gneiss, has a very distinct structure. The feldspar and quartz are about equally developed, and neither plays the rôle of groundmass to the other. The elements are smaller than in the granites, but much larger than in the gneisses of the district. The quartz often occurs as rounded grains, of which many are included in the feldspar. There is also a considerable quantity of brown mica, which assists in the foliation. This, however, is principally produced by the presence of a dusty mineral, with well-marked cleavage, which will not extinguish as a whole, and which looks like an altered sphene. The rock is also richer than usual in accessory minerals, zircon occurring in the quartz, and apatite in the feldspars.

The quartzless group of these rocks is more local, being found only in the neighbourhood of Llecheyn-farwy. It is difficult to give a name to these rocks, of which the bulk is feldspar and a large proportion plagioclase, while the other minerals have undergone a change into chlorite or calcite. Such is the rock near Llecheyn-farwy church (124). Its large close-fitting feldspars are thoroughly speckled with small crystals of calcite or sericite; there are a few scattered areas which may have been hornblende or mica, but are now mostly changed to chlorite, and there are zircon, apatite, and leucoxene as accessories. There is no observable alteration due to pressure.

Another rock of this type, at Ynys Dodyn (118), requires great caution. At first it appears to be in a fresher condition, but a closer examination indicates that it has undergone a cataclastic modification, with a re-formation of its crystals. Plagioclase is still the principal ingredient, and, in certain patches, it is much speckled and contains in the intervals between its crystals the remains of mica now altered to chlorite. These patches are separated by, and often isolated in, continuous areas of fresher plagioclase in which there is no mica, but epidote fills the intervals between adjacent crystals. Thus the speckled portions appear to represent the original rock, which has broken up, and the fresher feldspar has crystallised between and around the fragments. It is remarkable that, as in the case with the mica schists, the later pressure has produced spectral polarisation in the fresh elements, while the original fragments are left unaffected. There are other cataclastic forms of this type in the neighbourhood in which recrystallisation has not gone so far, which need not be further specially noticed.

Associated with the granites of this district are several quartz felsites, of which two have been examined from Tyn-y-Pwll (119) and Pen-y-carnisiog (114). It is by no means certain from their stratigraphical

relations whether these are apophyses of the more crystalline rock, or dykes within its substance; on the whole, the former appears more probable. They consist of a rather coarse groundmass of felsitic elements with large idiomorphic crystals of quartz, twinned orthoclase, plagioclase and mica. The latter rock has much more sericite in its finer groundmass. They are thus 'microgranites.' The porphyritic elements, or 'insets,'¹ are not always simple crystals, but crystalline aggregates of felspar and quartz or mica, so that it is 'glomeroporphyritic.' Most of the felspars are speckled with small crystals, and the quartzes show spectral, or even microspectral, polarisation. The obvious connection of these insets with granite seems to show that these are not ordinary quartz porphyries, but special modifications of the granite itself.

Another important, though small, area of granite exists in the neighbourhood of Pen-bryn-yr-Eglwys, in the north-west. The chief peculiarity of the rock here is the almost entire absence of any micaceous element, except such secondary mica as has been developed in well-marked cracks. The freshest rock of the district is behind the farm of Monachty (44). In this the quartz and felspar, most of which is plagioclase, are of equal importance, crystallising simultaneously in large plates, and occasionally inter-growing pegmatitically. The quartz is much cracked, and shows occasionally some spectral polarisation, and a few of the felspars are speckled; otherwise it is hard to discover any changes which have taken place in the rock, which is as good a granite, or rather aplite, as one could conceive. It only requires the presence of epidote to bring it into close agreement with the rock of Bryn-y-garn, St. Davids. This same rock at its junction with the surrounding sedimentary rocks (43) loses most of its quartz and becomes brecciated. Its enclosing rock is finely granular and sericitic.

Nearly as clean a rock as the above occurs on the north side of Pen-bryn-yr-Eglwys (40), but much of the quartz is here disintegrated into smaller elements, and there is some apparently original mica. The accessory minerals observed in these are some small needles of apatite, and minute rhombohedral or hexagonal crystals of brilliant red hematite, a few crystals of pyrites, and very rare zircons. All the other examples from this district are merely cataclastic modifications of this. In one, obtained from what was supposed to be the junction of the granite with the surrounding rocks (41), there are numerous and closely set, somewhat parallel, cracks now filled with mica, so that the rock is a kind of false mica schist; but it is pretty certain from this that the true junction is not here seen. Finally, on the northern side of the hill, close to an important fault (42), the slide shows an indiscriminate mixture of granite fragments and dust, in which there is no regularity whatever. These observations show that the neighbouring schistose rocks are derived by dynamic agencies from the granite, and not the granite from them. They also show how far these changes may go without our losing sight of the previous condition and structure of the rock. With these granites are associated certain felsites, which seem in the field to take its place. One of these near Pant-yr-Eglwys (35) does not differ particularly from an

¹ No satisfactory name for the crystals in a porphyritic rock has yet been proposed, and a paraphrase has always to be adopted. The name used by the Germans is 'Einsprengling,' and the nearest English term available corresponding to this would be 'inset,' which it is therefore proposed to use instead of porphyritic constituent.

ordinary felsite, with insets of eroded quartz and felspar in an indefinitely crystallised groundmass. But in others, as on the east side of Pen-bryn-yr-Eglwys (37), and at Pant-yr-Eglwys (33), proved to be felsites by the occurrence of numerous, though altered, insets, the groundmass is composed of definite round elements, all of the same size and substance, and divided by thin lines of sericite. These elements are so much like grains that, except for the insets, the rock under the microscope might be taken for a sedimentary one.

In the district south of Traeth Dulas the best preserved granite is a beautiful white rock (139), which microscopically appears quite fresh. It is characterised by its glistening white mica, most of which appears to be original. But in spite of its fresh appearance it is much broken up, and fresh mica is developed along the cracks, the spectral polarisation is strong, the quartz is disintegrated, and a confused orientation is introduced. It is, therefore, more or less cataclastic.

The rock at Llyn Trefwll (55) is still more cataclastic, though destitute of mica. The débris are very small, and only a few grains of epidote break the monotony. The rock from this neighbourhood, examined by Professor Bonney, appears to have been less broken. There are granites also in the group of rocks to be next discussed, but they will be best dealt with in connection with their surroundings.

2. *The Volcanic Group north-east of Parys Mountain.*—This is a marvellous group of rocks, quite unlike anything else in the island, or even, perhaps, in Britain. On the large scale, there is no regularity about them; but they seem to become crystalline in lumps and patches with no definite boundaries, but shading off into earthy-looking or sericitic rocks. Neither their stratigraphy nor their structure, however, suggests that the more crystalline portions are 'eyes' produced by the relative motions of the several parts; but give more the idea of their being a volcanic complex of fused and clastic materials. They are not all suitable for microscopic examination; but such as are, though they may be earthy in appearance, turn out to be crystalline in structure, and the irregularity of the mass is mirrored in the irregularity of the elements. They may be divided for description into two groups, according as the component elements are large or small. Those with larger elements have a crystalline appearance in the field, and some may be classed as granites and some as diorites.

The granitic type is well seen at various places on the shore, north of Porth Lygan (233). It consists of large masses of quartz divided by sutural lines, and equal masses of felspar which are occasionally idiomorphic, but are now so speckled as to be composed of little more than sericite and calcite, while many of them are banded. Between these two, isolated in their midst, and fitting closely against them, are patches of both brown and white mica, which are, therefore, judged to be original. The rock is therefore a typical granite, showing no signs of pressure, and has no schistose associates. Yet it is of the same type as the other granitic rocks of the island, both in the bands of the quartzes and in the alterations of the felspar, and differs chiefly in the absence of accessory minerals. When, however, this granite is broken, as at Pen-yr-Allt (244) garnets are found in it, though in such a state of alteration, as already explained, that little of the original mineral is left.

Those rocks on the east side of Parys Mountain, in the band that lies to the south of the main development of the group, that may be referred to the granitic type (252), are, like the rocks near Llecheyn-farwy, more

basic in composition. They contain no quartz, but are principally composed of large crystals of plagioclase, with some possibly original mica. It is, however, irregularly cracked, and the cracks are filled with mica and with a certain amount of hornblende of apparently secondary origin. This is closely associated with the rocks of dioritic type, which, as elsewhere in the island, are of a schistose character, apparently owing to the tendency of the hornblende to orientation. In one example examined (249) this mineral is very abundant, and is certainly of the same generation as the accompanying plagioclase, both being clearly crystallised and of equal importance. There is also abundance of isolated, and therefore probably original, brown mica. Quartz occurs sparingly, both as separate elements and as small inclusions, in the mica. The accessory minerals are numerous and important, including apatite and ilmenite, and a few crystals of sphene. Another example (251) contains the largest crystal of sphene seen anywhere in Anglesey. All the elements of these rocks are smaller than those of the granites. It is difficult to be certain of the origin of these schistose diorites in this locality, their stratigraphical relations being obscure. They are probably unconnected with the granites and later in date. Their basic character, their accessory minerals, and their association, all speak against their being developed from the neighbouring sedimentary rocks, as supposed by Mr. Allport. They show no signs of pressure.

We can in fact observe what may well be considered as the true sedimentaries in the immediate neighbourhood (250), and these are of an entirely different character. They are slightly orientated, and are composed of rather rounded elements of quartz, mica, and felspar, much of the latter being plagioclase; and in general they closely resemble the gneisses of other districts. It is probable that these are the rocks which formed the ground out of which the volcanic products were erupted.

The small-grained rocks of the district are exceedingly various, and it seems almost impossible to classify them, each one examined being different to the others: Moreover, their structure is utterly irregular, being nothing but a confused mixture of various minerals; according to the collocation of these minerals so is the rock. Very few, however, show any signs of pressure. In one group there is much secondary mica. Of these there is a beautiful example at Abertywedog (239), full of dark mica, interspersed with ferrite, and containing also quartz in irregular patches and sericitised felspar. Its chief peculiarity, however, is its containing the beautiful decomposed garnets, already described, some of which are large enough to occupy the whole field of view. In another of the same micaceous type, at Penrhyn-glas (246), and which also contains some ilmenite, the decomposed garnets are so abundant as to almost play the rôle of groundmass to the other elements. The others of this group take their character from the principal second ingredient. Thus at Llanwenllwyfo (242) we have a micaceous rock, in which the principal mineral is quartz, with apatite and brilliant zircons. In one south of Nebo (247) the principal mineral is sericitised felspar, with apatite and ilmenite; and in one at Dulas (237) the quartz and felspar are about equal in amount. One of the rocks of this group, at Porth Lygan (235), exceptionally shows feeble signs of foliation. It has abundant brown mica, with sericitised felspar, small scattered elements of quartz, with ilmenite or leucoxene, and another mineral, now utterly altered and decomposed, but which occasionally shows the cleavages of hornblende.

This may be compared with the hornblendic granite already described. In another rock near the same spot (236), but close to a crystalline mass, the whole mass has been broken up into fragments or torn out into strings. The best interpretation which can be suggested for these is that they are irregular masses composed of the materials of a granite in the form of volcanic *débris*.

A non-micaceous group has some quartzose representatives, as at Abertywedog (240), where the other elements are fairly preserved plagioclase and calcite, with a little leucoxene and apatite; and also some which are quartzless, as to the south of Nebo (248), where the rock consists of an irregular aggregation of plagioclase and calcite without definite boundaries. It also contains a considerable quantity of sphene, and a small amount of apatite and garnet.

Besides the above, which are composed more or less of granitic elements, there is associated with them in the same complex, and apparently of the same general age, a group of rocks which in some cases is certainly, and in others probably, pyroxenic. The clearest of these, at Rhos Manarch, inland (243), may almost be called a dolerite, though the general arrangement of its elements is very like the irregular rocks described above. It contains abundant augite, in broadish plates of irregular eroded outline, and also, to judge by the cleavage, similar plates of diallage, associated in an indefinite way with unbanded felspar, together with small sphenes and garnet. It is full of crystalline calcite, and has a skeleton crystal of pyrites. The former of these may well be secondary, as a similar mineral fills the numerous cracks. Of the others, owing to their state of decomposition, it is not so easy to be certain. One at Trwyn (241), which forms a beautiful object with the paraboloid and is somewhat orientated, has a groundmass of sericitic material, which from its arrangement may be the result of the entire decomposition of some felspar; with this are long patches of minute and feebly polarising elements, not unlike serpentine, which are also probably the result of entire decomposition of a second mineral. These spaces are scored with parallel cracks, now filled with calcite, whose crystals on either side eat into the adjoining spaces. Thirdly, there are some opaque areas of brownish dust, crossed by lines which appear to indicate a cleavage such as that of augite; and, lastly, there are many sphenes. Though utterly decomposed this appears to have been a holocrystalline rock of felspar and two pyroxenes.

There are two other rocks in this district which it does not appear possible at present to classify with certainty, though both are well-defined in their peculiarities. One of these, at Abertywedog (238), has a groundmass of garnet, much clear quartz in rather rounded elements, with inclusions of zircon and apatite, irregular patches of calcite, and crystals of decomposed sphene with brownish sub-opaque patches like worn crystals, with numerous parallel lines of brown dust, which seem to indicate a well-marked cleavage, such as that of diallage. In this the quartz, like the garnet and the calcite, may be secondary and adventitious, but at present, if the dusty material be diallage, it has not the associates we should expect. The other, from Porth Lygan (234), consists of uniform, small, rounded elements, apparently of felspar, with the narrow crevices filled with slightly orientated sericite. From the occurrence of insets in a similar rock at Pant-yr-Eglwys we know that this must be an altered felsite, but it looks more like one composed of minute lapilli.

This complex of various rocks is for the most part bounded by

faults, so that we have little opportunity of comparing them with neighbouring sedimentary types. One, however, of this class, from the northern side at Ty Newydd (245), has been examined, and is seen to differ essentially in structure, and correspond to the more altered gneisses. It consists of larger elements, bounded by dark lines, probably due to decay, of rather rounded outline and closely fitting. The larger ones are felspar, and the smaller quartz, and orientation is produced by abundance of brown mica. It contains also a lapillus of a rock, consisting of a mixture of quartz and sericitised felspar in small elements. This so closely resembles in general structure the supposed sedimentary rock from the east of Parys Mountain, that the conclusion is strengthened that these are the true sedimentaries, and the group of rocks above described are of special and volcanic origin.

3. *The Dioritic Rocks and their Allies.*—The Dioritic type of rocks, besides those described in connection with the last group, occur in large quantities in the Central and Eastern districts, and to a small extent, in connection with the granite, in the north-west.

In the Central district there are various patches between Craig-yr-allor and Plas Llanfihangel. At Craig-yr-allor itself (130) the rock is very rich in hornblende, and consequently has a dark-green colour. The crystalline elements are small throughout, and individually are very irregularly arranged. The rock, however, in hand specimens shows some confused orientation. The feldspathic elements, which are now entirely converted into sericite, play the rôle of groundmass, and in these there are dusty patches of the decomposed and not yet recrystallised felspar, in one of which the twinning lines may still be seen. The hornblende is scattered over this without crystal outlines, and the rock is very rich in sphene in small crystals and patches, with an occasional nucleus of ilmenite. In certain spots there is a pyroxene, which occurs in a similar manner to the hornblende, but less conspicuously. In one case it appears to form part of a hornblende crystal. It would appear, therefore, not improbable that the rock was originally a dolerite, in which each mineral has changed to its appropriate substitute, and the whole become somewhat schistose in the process. In another rock from the neighbourhood (131) there is a more conspicuous banding by the irregular segregation of the hornblende and felspar. The latter is often scarcely altered, but may be traced gradually becoming sericitised. The former is very clean, and the only signs of pyroxene are some apparent inclusions in certain of the crystals. In its other features the rock agrees with the above. The rock on the summit of the craig itself (128) is a much finer-grained rock, and is only very obscurely orientated. Here the small, rather rounded felspar elements are very clearly seen, and the hornblende is clearly crystallised, and the titaniferous element is represented entirely by ilmenite. It would appear, therefore, that the rock is less altered as a whole than the first described. Yet, if it be really derived from a dolerite, it is remarkable that the only sign of pyroxene occurs in minute corners and specks at the edges of the hornblende. As far as the evidence of these rocks themselves may go, they show no sign of disturbance since their first consolidation, any alterations observable or suggested being entirely chemical. But in another rock in the district (129) the whole has been broken into fragments, the larger ones lying in a cement of the smaller ones, making a true mortar-structure. Yet the large fragments are very clean, the felspar is well preserved and contains inclusions of apatite, and

the hornblende is well crystallised. A second rock from the northern boss (132) has the change carried still further and combined with the chemical, the whole rock being an irregular mass of calcite and chlorite, with stray fragments of unaltered felspar and hornblende, to show whence it has been derived.

The rocks which lie to the north of Llandrygarn, though well supplied with hornblende, appear to belong to a different group, more nearly allied to the granites. Two of these, one near Llandrygarn (133), and the other near Penterfyn (134), are very much alike. In these the felspars are in much larger elements, and often contain apatite, and there are isolated areas of quartz. The hornblende, mica, ilmenite, and sphene which make up the rock crystallise only in the intervals, and have therefore what may be called negative outlines. A similar type of rock occurs in the valley south of Llecheynfary. The band of diorite which extends northwards to Plas Llanfihangel has been examined near the latter spot. It represents the Craig-yr-allor types in rather larger elements. In the rock to the south-west of the farm (136) the hornblende and felspar are about equal in amount. The latter is much sericitised and contains a little apatite, and the former has in many places pyroxenic patches taking the place of a part or the whole of the crystal. There are also some dark brown rutiles. The rock to the east of the farm (137) is one of the most complex in the island. It has a kind of groundmass composed of a complex of small and very irregular elements of quartz and felspar, the latter being the most abundant and often occurring in large sericitised plates and containing apatite. The hornblende is in large patches, each of a single crystal, generally decomposed along the cleavage lines, and without definite boundaries. There are several well-preserved patches of augite, some of large size, and not in this case connected with the hornblende; there is a considerable amount of the usual sphene; and, finally, there are large ophitic masses of the ordinary garnet. Some short, dusty, high refracting pieces may even represent decomposed rutile. If this rock commenced as an ordinary dolerite, chemical metamorphosis could hardly go much further.

It is remarkable that at Pen-bryn-yr-Eglwys we have, in a small band, the two varieties which are seen to occur in the Central district; one of these (38) is the coarse form, such as occurs north of Llandrygarn. It has a groundmass of well-banded plagioclase in large elements, with little crystals of apatite; and the hornblendic element, which is in irregular, lenticular, and somewhat orientated bands, is now entirely converted into chlorite; the mica also which was present is mostly now in the same form; but there is no quartz. The other (39) corresponds entirely with the finer rocks at Craig-yr-allor. There is the same uniformity of size and distribution of the small elements; the felspar is apatite-bearing, there is the same unaltered ilmenite; but the hornblende, readily recognised by its cleavages and general build, has now, as in the last case, been entirely changed to chlorite.

When we put these observations together, and call to mind the various alterations traceable in these rocks, both mechanical and chemical, which succeeded the presence of hornblende within them, we may be certain that, if this hornblende has ever been derived from an augite, the change must have taken place at a very early period, and under quite different conditions to those which have brought about the later changes.

In the Eastern district there is an important mass of diorite in the

neighbourhood of Gaerwen, essentially of the same nature as that at Craig-yr-allor, but more foliated throughout. The closest resemblance is in the so-called 'gneiss' by Holland Arms (175), which has the same uniformly distributed small elements of felspar and hornblende and numerous minute sphenes. Some few of the hornblende elements have small corners which present the characters of a pyroxene; but their long axes are all in the same direction, and they are not deformed. In every other case examined the elements have been more or less pulled out into lenticles, whereby their aspect is greatly changed. The first stage of this process and its results are beautifully seen in the rock at Gaerwen Windmill (173). Here the hornblende has become rather fibrous, but is otherwise little changed except in shape; but the felspar, assuming it to have been originally present, is now in the form of dusty, not very transparent lenticles, which have the optical characters of epidote. These have parallel sides for some distance, and then terminate gradually. The quartz which was present is found in microspectrally polarised bands. There are also the usual sphenes and a little pyrites. Some later veins in this rock are of interest, being composed of clear felspar, with needles of actinolite (?) radiating from the ends of the hornblende layers. In a rock at the most northern end (182) we find a second stage. Here the same elements of hornblende, epidote, and sphene can be seen to be present, but the rock is now crowded with mylonitic lines, between which the epidote is ground to powder, and only a few recognisable fragments of hornblende are left. It is strange that this shearing should not have been followed by any chemical changes, especially as there are transverse cracks filled with calcite, and a very low polarising mineral, perhaps serpentine. In this case the strain has acted so as to intensify the foliation; but in a rock from the wood north of Y-graig (179) it has broken it up, so that orientation can only be observed in small fragments. It is remarkable that no epidote can be observed in this rock, the feldspathic element having broken up and become microspectral or mosaic.

The interpretation of some other rocks of larger elements will now be easier. There is a banded rock composing the hill north of Y-graig (178) in which dark-green bands alternate with white ones. This corresponds on a larger scale with the rock at the windmill, the green bands being elongated hornblende, and the white ones decomposed epidote much broken up. The rock at Ysgubor Llwyd (180) is of still larger elements, difficult to identify: some are certainly hornblende, and others epidote and felspar, but there are large porphyritic crystals with strong cleavages in one direction, and others occasionally cutting them at $87\frac{1}{2}^{\circ}$, and the extinction makes an angle of 14° with the first. It may be a felspar. Another is colourless and non-dichroic, in long flakes like mica, with cleavages in the same direction, and the extinction making an angle of 18° with these. It may be a pyroxene. The rock has been much broken. A third, to the north of Holland Arms (181), is almost entirely hornblende, in large frayed-out crystals with spectral polarisation, a phenomenon rare in this mineral. A few narrow lenticles of epidote, and crystals of sphene bring it into the same group as the rest.

The rocks in the narrow band which runs up to Pentreath can be at once compared with and understood by the aid of that at the northern end of the 'gneiss' area. One, at the crossing of the Beaumaris road (183), which is entirely cataclastic, shows some relics of hornblende and epidote, but the intervals are filled with calcite. In the rocks nearer

Pentreath (184) almost all the hornblende is gone, and very little epidote is left, and this is in dust-like fragments—the base has crystallised into microspectral felspar. The end of this long series could scarcely be more different from the beginning than it is.

Besides these coarser-grained rocks there is in this district a remarkable series which is schistose in the highest degree. The connection between these and the others is easily traced through a rock just to the south of Y-graig (177), or one at the back of Gaerwen Windmill (174). In the former we have very long and narrow crystals of hornblende of no definite shape, and small isodiametric crystals of epidote and quartz, and there are also a number of minute brown rutiles. All these are perfectly clean and fresh, and do not appear to have been in any way modified since their formation. In the latter the hornblende has more shred-like ends, the epidote is elongated, and there are only a few minute sphenes. They thus differ only from the former group by their much more marked orientation. It is essentially the same rock as this which occurs in an intrusive form in the Llangaffo cutting. Much of this is highly orientated, though the specimen examined (164) does not show this well, but has larger hornblende crystals, inclosing more or less isolated areas in which there is little but epidote and quartz. From these we pass to a rock at Tyn-drain (167), which agrees with them in every respect, especially with the one at Gaerwen Windmill, except in the replacement of the ordinary hornblende by beautiful blue glaucophane. It contains, however, some scattered elements of speckled felspar and of hornblende, which do not conform to the general orientation. From this, again, it is but a step to the glaucophane schists of the quarry near Anglesey Monument (168, 169), in which that mineral is more pulled out and interfelted, and is in such abundance as to almost play the rôle of groundmass to the epidote. There is little else than these two in the rock, only a few specks of hematite, and some probably segregation veins of quartz. In the latter float some separated crystals of glaucophane, which may either have been torn from the sides or re-formed with it. The orientation in these rocks cannot be properly called foliation, since it has, at present at least, no relation to a plane, but only to a line—i.e., there is no orientation in a transverse section. Many of these rocks have been examined from various localities, but, with the exception of those that follow, none show any essential difference from the above or peculiarities worth noting. In a rock from near Castellor (172), and another from the south of Newborough (164), there are enclosed small spherical areas, bounded by ferric dust and filled with complex growths of epidote, like the smaller vacuoles figured by Fouquet and Lévy in the 'Variolites.' In another rock, near Castellor (171), one of the quartz veins, as already noted, contains small prisms of tourmaline. Like the group with larger crystals, these can undergo still further changes under the action of pressure or stress. Thus, at Carnen Goch (170) the hornblende is torn out in shreds, the epidote is broken up and elongated, and there are numerous cracks and veins of feldspathic and calcitic crystals. Near Holland Arms (176) the lines of orientation are so contorted and crumpled that they can scarcely be recognised under the microscope, but are evident without it. Finally, at Bryn Gwyn (165) (see fig. 24), and elsewhere on the eastern margin, the elements are so pulled out that they are reduced to little more than dust, and the rock looks little better than an earthy slate.

In the extreme north the rocks are of the same character as the last described group, but not glaucophane bearing; but their regularity is much interfered with, and the cracks and intervals are filled with fresh quartz or felspar. This is well seen in the rock at Ty Lon (185) and on the summit of Mynydd Llwyddiart (185), and in these perhaps we see the maximum change of the series.

4. *The Gabbros and Serpentine*.—These rocks having been already systematically studied and described by Professor Bonney, there is the less necessity for dealing with them at length. The existence of gabbro as well as serpentine in the area has been proved, and the derivation of the latter from olivine-bearing rocks has been demonstrated. Nevertheless, the present examination has brought out some additional points of interest. The gabbro at Ty Newydd, near Four Mile Bridge (45), is a well-marked rock. The numerous diallage crystals now stand out porphyritically from the groundmass; they are fairly well preserved, and have secondary enlargements which are not optically continuous with the original crystal. Two minerals at least contributed to the groundmass. One, which was probably the felspar, is now represented by opaque dust, the crystalline aspect of which with the paraboloid suggests its previous conversion into epidote. The other mineral has produced transparent patches, which show a fine fibrous or closely cleaved structure, parallel to which it extinguishes. It may therefore have been an enstatite.

Starting with this normal rock we may now by several steps trace its passage under the action of pressure and shearing into a schist which may easily be mistaken for one of the ordinary schists of the island; thus confirming the suspicion of Professor Bonney with regard to the schistose rock of Tyddyn Gob, that it might be 'an altered gabbro with pressure foliation.'

In the rock at Dinas Fawr (46) the diallage looks still more porphyritic from the groundmass having passed over entirely into a microspectral mass, in which all individualisation of the original felspathic crystals is entirely lost, and the whole has become saussuritic; where it has been pulled asunder the interstices are filled up by growth from the surrounding diallage crystals. The indestructibility of the diallage in the midst of these changes is noteworthy, and assists greatly in the chain of evidence which leads us at last to the schists. The next link is at the same spot, and forming one large knob with the last (47). This example is almost entirely composed of fine crystalline strings, tailing off, or interosculating with each other, and having the pulled-out look characteristic of mylonites; but amongst these are some distorted fragments of diallage. As diallage has nowhere else been found than in the gabbros, its occurrence may be taken as evidence that the rock has been derived from its neighbour by mechanical deformation. The proof of this depends on the indestructibility of the diallage. But the diallage is not entirely indestructible. In the former rock the slight alteration of the diallage produces crystalline fibres, and in the latter the abundance of these is correlated to the few relics of the original mineral. These fibres appear to be of the same nature as those which produce the 'soapstone,' so that we may call them talcose. The origin of these talcose schists at this spot is certainly from diallage-bearing rocks. We must therefore be prepared for further chemical changes. In the next rock of the series, at Yr Hendty (48), the diallage is entirely

converted into the talcose material, which is mostly in fibres, but occasionally has a fragmental form with diallage cleavages. This material is in porphyritic patches. The remainder is partly mosaic felspar and partly epidote, the latter in patches which are obviously cracked, drawn out, and separated. Thus our eyed gabbro has become a talcose epidote schist. Here, however, the original positions of the diallage crystals are still indicated, so that the rock at Penrhyn Fadoc (49) is a still further stage. In this epidote is very abundant, but it occurs not only in pulled-out bands, but in scattered recrystallisations lying in clusters in a groundmass of the talcose fibres. The freedom of certain spots from these new crystals is the only indication of where diallage has originally been, except that by good fortune one or two small fragments of the unaltered mineral are actually left. Finally, in the rock in the railway cutting (50) (see fig. 23) there are wisps of talcose fibres, like cirrus clouds, flashing out on a dark background, consisting of broken and drawn-out fragments of epidote, now ground to opaque dust or partially recrystallised to form mosaic felspar.

These igneous mylonites, whose origin is thus demonstrated, however schistose they may be, nevertheless differ entirely from the neighbouring schists of the island both in their chemical constitution and in the character of the orientation that affects them. For this reason it is probable that the soapstone at Pwll Clai (54) is not an altered schist, but is derived from the decomposition and recrystallisation of one of the gabbro group, in association with which it occurs. It consists, like the last described, of talcose fibres, small mosaic felspar, and a few epidote crystals; but it is much cleaner, and though it has been a mylonite by the general arrangement of its lines, it has since that time recrystallised.

Of the serpentines, the most typical observed is from the base of the first inlet south of Four Mile Bridge (51). In this the original crystals of olivine can still be seen in outline in certain parts, floating in a transparent matrix, which is of apparently later origin. Fitting in with these in a holocrystalline manner are several areas showing the fine fibrous cleavage structure of enstatite. The ferric constituent is not found distributed in the cracks, but occurs chiefly in the form of rounded masses like eroded crystals, or scattered like dust, both in the olivine areas and elsewhere. The alteration of the olivine has taken place along lines which have a tolerably uniform direction throughout the rock, and which pass through the enstatite patches. We may therefore conclude that they were produced by the general forces which have brought about the foliation of the district, and that the rock is in fact a foliated serpentine, which was once a Saxonite. From the primary lines of alteration in the olivine areas a transverse set of lines has proceeded, so that the whole crystal is changed into a series of broken parallel bands of chrysolite. The enstatite areas, on the contrary, though roughly traversed by the general lines, have their fibres arranged along, and perpendicular to, the most conspicuous cleavage lines. The intervening matrix must be of later date than the primary alteration, as it interrupts the parallel lines; it is composed of indefinitely small fibres, doubtless serpentinous, which, being arranged promiscuously, scarcely have any effect on polarised light. The whole is re-cracked in many directions, and the new cracks filled with serpentine. The metamorphosis of the rock does not seem, therefore, to have followed the usual course.

Another totally distinct form of serpentine occurs near Cruglas (52). Quite half of it is composed of very minutely crystalline calcite or dolomite, not forming a mosaic, but speckling the whole rock in clumps. These clumps are in some places irregular, and in others occupy more definite shapes; the remainder, or groundmass, is of crossing fibres of serpentine of various sizes and dispositions. There is also much black magnetite, sometimes forming the centres of patches surrounded by cracks, but never occurring in the cracks themselves. This calcite is doubtless an infusion from neighbouring calcareous rocks, and has assisted in the alteration of the rock. At first sight it seems impossible to recognise any original minerals; but towards the circumference of the slide are seen calcitic areas which are outlined in such a way as to suggest the original presence of augite; and in one case there is a section without calcite, distinguished from the rest by its transparency, and having very distinctly the section of a crystal of augite, cut perpendicularly to its vertical axis. This remains dark between crossed Nicols, and gives a biaxial cross in convergent light. In another case a crystal of the same shape and properties has narrow lines of calcite along the nearly rectangular directions of cleavage. These we may safely consider to be altered augite. In certain other areas the calcite is seen orientated in the direction of the longest axis of the original crystal, and the serpentine is also separated along lines parallel to this. It is probable that these areas represent enstatite. It is not so easy to recognise the original olivine, but when the slide is examined with a hand-glass, there is evidence that half of it is occupied by a single large crystal lying in the centre. A portion with a yellower tint than the rest is outlined by a polygon; and it is always beyond this boundary that the indications of augite and enstatite occur, while within, all is characteristically irregular. If the nature of this be rightly judged, the original rock was a porphyritic Llerzomite. It is now an opicalcite.

In the above rock the neighbouring calcite has affected the serpentine; in another close at hand (53) the converse phenomenon is seen. Of this the same calcitic crystalline material forms the bulk, but there is nothing in any way to suggest previous crystals whose place it has taken. On the contrary, the whole is traversed by irregular, undulating, subparallel lines of magnetite, from which, as also from minor cracks without magnetite, the serpentine crystals grow out in radiating sheaths. This is most easily interpreted as a recrystallised limestone, into which serpentinous matter has been infused from without.

5. *The Isolated Masses and Dykes.*—For this section are reserved all such peculiar rocks as are either known from field evidence to form dykes, or occur in so sporadic a manner that they are probably of similar origin to dykes. No dykes, however, that are intrusive into Ordovician rocks, or are similar in character to such as are, will be included. For all that is known to the contrary, all the following rocks *may* have been produced before the commencement of the Ordovician period. We may commence with the felsites.

No felsites have been recorded, or have been observed by the writer, in the Eastern district, and those that occur in the Western and Central districts, and that south of Traeth Dulas are so intimately associated with their respective granites that they have scarcely a separate existence. Thus the only isolated felsites occur in the Northern district, of which four have been examined.

The first is from a dyke east of Mynydd Mechell (225) (see fig. 20). In this there are no proper insets, but here and there are little collections of epidote crystals—sometimes almost isolated and sometimes attaining the magnitude of a fair-sized spherule—but they are not radiate, nor regular in outline. The groundmass, as seen by the paraboloid, looks like an almost uniform glass, but dim and shadowy outlines separating very feebly dotted spaces indicate a subdivision into larger elements. When seen between crossed Nicols these larger elements are still conspicuous as a kind of substratum, or earlier stage of division; but they are greatly interfered with by the development, with sutural boundaries, of numerous smaller crystals, whose long axes are in general irregularly arranged, but which in many spots radiate from a point, like ill-formed spherulites, or from the circumference of the epidote nests. This combination of larger elements with smaller spherulitically arranged ones is so peculiar that if it is met with elsewhere it should receive a name, such as *macro-felsitic* structure. In a second dyke from the same district (226) the groundmass is microgranitic, and there are no insets or epidote nests, but it is crowded with large spherulites of the ordinary fibrous radiating type. These have occasionally successional rings; where most crowded the interspaces are filled with larger elements. Its present state has therefore been reached by at least two stages. The rock at a large boss at Tygoch-wyfsa, east of Amlwch (230), is a typical microgranite, whose insets are idiomorphic quartz and twinned orthoclase, which are often surrounded by a spherulitic border. The most beautiful of all these rocks, however, is that of Hafod-onen, south of Amlwch (228) (see fig. 21), marked on the Survey map as 'greenstone.' Its original structure is rather obscured as seen between crossed Nicols, but with the paraboloid it is seen to be truly porphyritic, all the insets being felspar and most of them idiomorphic, and some speckled. In the groundmass there is a little microgranite, but the characteristic structure is that of a beautiful granophyre. The elements composing this are very minute, and are arranged with the longer diameters of several in succession in one direction, so as to form a lacework pattern. The difference between the materials of the elements cannot be demonstrated between crossed Nicols, but by oblique light there is seen to be a difference in the refractive index. The structure is therefore that of a true micropegmatite. In many cases the network starts from the sides of a small rectangular inset and grows out in bushes, forming an hour-glass pattern in the mass, which is bounded on all sides by similar growth from other crystals. They thus form the pseudo-spherulites of Rosenbusch, with this difference only, that their outlines are regulated by the interference of neighbouring growths and by the size and shape of the originating crystal.

Another group of rocks consists of those which weather spheroidally, and all of which have a more or less common structure. One of the simplest is largely developed among the volcanic rocks of Careg Gwladys (206). In this there is an abundant base, which remains dark between crossed Nicols, but it is scarcely a glass, to judge by its dusty appearance in ordinary light, but it may be microfelsitic—there are a few minute polarising specks in it. In this groundmass are scattered numerous microliths of a lath-shaped plagioclase, which, from its low extinction angle, is probably oligoclase. These lie in every direction and interlace with each other without any regularity. We have thus the absolute reverse of orientation, seeing we start with axial crystals. To distinguish this we may compare

it with the arrangement of spicules in some sponges, and call it *spicular* arrangement. In the same district we find a more complex form (207) (see fig. 22), which may really be the same rock under different and special circumstances. It is seen running into the crevices and wrapping round the surface of a purple calcareous rock, and is characterised in the hand specimen by a number of small pea-like bodies which are brought out on its surface by weathering. The base of this is also a dusty substance with minute polarising specks, in which are scattered very fine felspathic microliths, which are in general irregularly placed, but in some places they aggregate into sheaths, and elsewhere, particularly near the contact with the shale, become complete spherulites, though without a circular outline. None of this structure, however, represents the pea-like bodies. These in a thin section form rounded areas, with a closely-set narrow border of minute epidote crystals, with larger crystals of the same, or of some other unrecognised mineral, filling the centre without any arrangement. They vary in size from .005 inch upwards. No particular information is afforded by this rock as to the origin of such varioles, as they ought probably to be called, from their resemblance to some of the structures seen in the Variolites of the Durance. We can compare them also with the epidote nests seen in the diorites near Newborough and in the felsite at Mynydd Mechell. There are also in the rock several areas now composed of an aggregate of epidote crystals, and having the external form of orthoclase crystals. These appear to be altered insets. There are also a few small patches of augite.

A third remarkable spheroidal rock occurs as an isolated boss to the west of Amlwch (227). The original structure of this can be best made out with the paraboloid. We thus see that it contained a number of acicular microliths, floating irregularly in what was probably a glassy base, but it is now filled with infinitesimal particles of a shiny crystalline appearance. These are arranged in relation to the microliths, often forming a border to them, and sometimes appearing to radiate from them. The whole mass is also separated into larger areas of very obscure and irregular outline, which polarise as a whole somewhat after the manner of the macrofelsite of Mynydd Mechell. But over and above all this the rock has a special feature, which is the most striking one on first examination, but which is evidently of secondary origin. This is the development of a crowd of small prismatic crystals of epidote, which stand isolated or congregate in groups and have no regularity of arrangement. That they are of later origin than the microliths is proved by their often wrapping round and partially enclosing them. There are also a number of calcitic patches and lines of ferric dust.

It would seem from the structure of these rocks that an irregular arrangement of long narrow crystals is the most favourable for the development of large spheroids by weathering—the structure and the form being alike peculiar, and in every case combined. It may be called to mind that such is the structure of basalt, which is also noted for its spheroidal weathering. The spherical surfaces are, of course, anterior to the weathering, which only brings them out, and it is not suggested that the spicular structure is the *cause* of these spherical shells, but that the two are correlated as the double results of a single cause. If from the circumstances of cooling, or the materials of the rock, a spicular structure is brought about, it is probable that a spheroidal form will follow.

A peculiar rock at Gwalchmai (138), which unfortunately is not seen in a weathered state but only in a quarry in the village, has essentially the same general structure as the above group, but it looks quite black, and like an earthy pelite. It consists entirely of rather larger microliths, crowded together and overlapping, and which also appear from their extinction angle to be oligoclase. They are set in a matrix which contains nothing but black and red ferric dust, and a non-polarising base. It might almost be called a basalt but for the absence of any magnesian constituent. Perhaps andesite would be the best name to apply generally to these rocks. The interest of this black one lies in the fact that it is the only one of its kind yet found *in situ* in Anglesey, whereas numerous fragments with a similar structure occur in the overlying rocks near Bangor and elsewhere.

The only remaining rocks whose structure the microscope is of value in elucidating, are the diabases. There are, of course, many such rocks in Anglesey of more recent date, but those now to be described are entirely confined to the oldest series. One of the most interesting is that near Llyn Trefwll, which lies between the chloritic schists and the great Ordovician beach breccias, and with which the small mass of granite already described is associated. Some of this is schistose, some is not. A non-schistose example (56) consists of a dusty, but otherwise transparent, base, in which are numerous felspar microliths as well as black specks, which may be magnetite; it is dark between crossed Nicols, but this is partly due to the development of a non-polarising chloritic substance. In this base are numerous insets of augite, many of the smaller of which are idiomorphic. There are also some patches of dark earthy matter, apparently included fragments. The rock is therefore a typical diabase. The schistose variety (57) differs in no essential respect from this, except that the augite is smaller, is scarcely ever idiomorphic, and looks fragmentary. The apparent schistosity is due solely to a few nearly parallel cracks, and an almost imperceptible orientation of some of the microliths. Apparently continuous with this rock is a green mass which contains fragments of granite (58). This green rock, however, is really a diorite like that of the Central district, rich in hornblende, with a little apatite. It is, therefore, probably unconnected with the diabase, and forms part of the breccia bound to it by pressure. This is the more probable, as the fragments of granite described by Professor Bonney were associated with a slaty matrix. In the neighbourhood of Dinas Llwyd, and northwards to Bodowen, there are numerous lenticular patches of igneous rock, which, unlike the later dykes, are orientated with the sedimentary rocks of the district, here largely of volcanic origin. One of these has recently been described by Mr. Harker ('Geol. Mag.' N.S. Dec. III. vol. v. p. 267) as an olivine diabase. The specimen examined for this report, from nearer Dinas Llwyd (127), would be rightly described by that title. It does not, however, show the ophitic character of the augite, which is described by Mr. Harker, but, like his specimen, it contains large masses of ilmenite, a characteristic mineral of the older but not of the newer rocks. It is probable for all reasons that this belongs to the older group, and in this case it is the only one in which olivine has been recognised. A mylonitic form of apparently the same type of rock occurs a little west of Llangwyfen (125), in the same district. It has drawn-out crystals of augite, plagioclase, and perhaps of diallage, in the midst of lines of

crystals composed of epidote, chlorite, and calcite, with a fibrous mineral elsewhere referred to talc.

A mass marked 'greenstone' on the road between Amlwch and Parys Mountain, protruding through the old schists like a neck (229), is another of these diabases. It shows a groundmass entirely composed of secondary epidote, in which there are many insets of augite, some of them idiomorphic, with large masses of leucoxene in the form of skeleton rhombohedra. This last fact, together with the total conversion of the feldspathic constituent into epidote, suggests that it is not much younger in date than the rocks amongst which it occurs.

There are several other masses of diabase which have either not been examined, or have been found so utterly broken down that little of their original structure can be made out.

CONCLUSIONS.

The series of rocks above described are so various in their composition and structure that the results of their study cannot be fully stated in a single proposition, but there are many conclusions of which they either afford demonstration or render the probability considerably stronger. It is of course understood that these conclusions refer only to the rocks of Anglesey, so far as this Report is concerned. These may be formulated as follows:—

1. The use of the paraboloid and binocular microscope throws new and valuable light upon the structure of such rocks.

2. The amount of alteration in rocks which form part of the same complex may vary very greatly without our being able at present to assign any adequate cause for the difference.

3. Rocks may become entirely crystalline without the slightest sign of foliation, a mosaic type of structure being produced, in which areas of yielding to tension may be seen.

4. Fine-grained rocks more easily become entirely crystalline than coarse-grained ones.

5. In those crystalline rocks which are most clearly connected with unaltered ones the crystal elements are small.

6. Foliation-cleavage is produced by the orientation of some of the new minerals, the others remaining unaltered.

7. Fracture-cleavage is produced by larger cracks, which are afterwards filled with mineral matter.

8. More complete foliation is unaccompanied by cleavage.

9. Original structures, such as that of lamination, need not be destroyed by foliation.

10. Very few, except fine-grained, rocks are entirely recrystallised so as to lose all trace of original fragments.

11. Rocks which under pressure have been contorted or cleaved may have their elements orientated in relation to the pressure, and not to the bedding.

12. In no case is perfect foliation known to obliterate the bedding, though there are foliated rocks whose original bedding is not certainly known.

13. The orientation of the minerals in a rock is of various kinds—quincuncial, linear, laminar, elemental, and confused—some of which are

more complete than others. This must have been produced under the action of a directed force, which caused no motion in the mass as a whole, and may therefore be called statical.

14. The effect of pressure on a crystalline rock is to produce spectral polarisation, and a further amount to produce microspectral polarisation.

15. In the case of feldspars, a structure closely resembling that of microcline is often found in rocks which have been subjected to pressure, and may be due to that pressure.

16. Pressure accompanied by shearing produces mylonitic lines, which may influence subsequent crystallisation, but which are quite distinct from ordinary orientation, the force brought to bear resulting in motion of the mass, and being therefore dynamical.

17. The pressure under which rocks have become foliated is greater than that necessary to produce microspectral polarisation.

18. Some of these ancient rocks have been produced by the agency of calcareous and siliceous springs.

19. The chemical composition of the rocks considered igneous is different from that of the general sedimentary rocks, and often includes special minerals.

20. The elements of the holocrystalline igneous rocks of acid type are of a different order of magnitude from those of the sedimentary rocks.

21. Such acid igneous rocks are of various mineral constitution and have undoubted felsites intimately associated with them.

22. Some of the most peculiar of the crystalline rocks are altered volcanic products without orientation.

23. The basic igneous rocks have a great tendency to foliation, and may become as foliated as any schist.

24. Some of the hornblende schists may be altered dolerites, without showing any signs of subsequent pressure or shearing.

25. The serpentines are derived from more than one variety of original rock, including saxonite and lherzolite.

26. Igneous rocks, including gabbros, have their mylonitic representatives, whereby they may become schistose, and the production of schistosity may be accompanied by chemical changes.

27. The difference in character between these and the regularly foliated rocks indicates a different form of pressure in the two cases, the latter being practically unaccompanied by shearing; and standing, as in the case of the sedimentary rocks, in the relation of a statical to a dynamical force.

28. Almost all varieties of rock have their cataclastic representatives, unaccompanied by any radical chemical change.

29. Many rocks have very long histories, the events of which have left their traces in the structure, and all of which may be subsequent to their foliation.

30. The dykes and isolated masses have peculiar characters—macro-felsitic, granophyric, variolitic, &c., distinguishing them on the one hand from the more ancient crystalline rocks, and on the other from the newer dykes of the district.

31. An irregular arrangement of minute elongated crystals—in other words, a spicular structure—is favourable for the production of spheroidal structure, as indicated by the mode of weathering.

32. Finally, the whole series of rocks presents many original forms which are still recognisable, and the metamorphosis they have undergone,

leaving evident traces in their structure, does not prevent our recognising in them a vast and varied complex to which perhaps there is no parallel in the later rocks of Britain.

LIST OF THE ROCKS REFERRED TO IN THE FOREGOING REPORT.

1. Great Quarry, Holyhead—Quartzite with foliation cleavage (fig. 12).
2. Porth-yr-Ogof, Holyhead—Quartzite with coarse groundmass.
3. Central series, Holyhead—Impure quartzite.
4. Porth-yr-Ogof, Holyhead, at junction—Impure quartzite with mica fragments.
5. Porth-y-felin, Holyhead—Laminated with parallel foliation (fig. 3).
6. Porth-yr-Corwgl, Holyhead—Showing solution of broken quartz (fig. 13).
7. East side of Straits, near Valley—Fine-grained rock.
8. Near Chapel, Four Mile Bridge—Fine laminated schist.
9. Caer Ceiliog, near Valley—Fine-grained rock, with mica orientated obliquely to a strain-slip cleavage.
10. Crossing of River Alaw—Coarse fragmental rock.
11. Peniel—Green dust rock.
12. Porth Dryw—Fine mylonitic slate.
13. Beyond Porth Dryw—Mylonised in direction of bedding, with large fragments.
14. South point of Porth Delise—Serpentinous mineral in tufts.
15. South point of Porth Delise—Irregular calcite with large mica.
16. Infusion south of Porth Defaid—Infusion of calcite and quartz with chalcopyrite.
17. South of Porth Defaid—Laminated schist.
18. Green, East of Llanfachreth—Fine-grained rock.
19. Abersant, Llantrissant—mica-schist with elemental orientation—zircons.
20. Llanddeussant—Fine-grained rock with mica orientated obliquely to a strain-slip cleavage (fig. 10).
21. North of River Alaw—Coarse fragmental rock, fragments mostly felspar.
22. Llanbaban—Mosaic rock with tension areas.
23. East of Bodedern—Fine-grained rock with abundant orientated green mica.
24. By Caer-deon, Llanddeussant—Fine-grained rock with tension areas.
25. Pont-scyphydd, north of Llanddeussant—Fine-grained rock, mylonised in the direction of the bedding.
26. Llanfaethlu limestone—Fine mosaic limestone.
27. Associate of Llanfaethlu limestone—Fine mosaic rock.
28. Church Bay—Fine-grained rock with large fragments.
29. Church Bay—Fine tuff.
30. Llanrhyddlad—Fine mosaic rock.
31. Summit over Ogo Lowry—Fine-grained rock with many quartzose fragments.
32. Hill over Ogo Lowry—Mosaic rock or marbled slate (fig. 4).
33. Pant-yr-Eglwys—Granular felsite.
34. Pant-yr-Eglwys—Dust rock.
35. Near Pant-yr-Eglwys—Felsite.
36. Quartz knob, Pen-bryn-yr-Eglwys—Quartz elements with sericitic boundaries.
37. Pen-bryn-yr-Eglwys—Granular felsite.
38. Pen-bryn-yr-Eglwys—Plagioclase and chlorite.
39. Near summit, Pen-bryn-yr-Eglwys—Chloritised (epi ?) diorite.
40. Pen-bryn-yr-Eglwys, north side—Granite with minute hematites.
41. Pen-bryn-yr-Eglwys, north side—Cataclastic granite.
42. Bottom of Pen-bryn-yr-Eglwys, by fault—Powdered granite.
43. Monachty, junction of granite and ash, Brecciated granite.
44. Behind Monachty—Aplite.
45. Ty Newydd, Valley—Enstatite gabbro.
46. Dinas Fawr, Four Mile Bridge—Gabbro with eyes of diallage.
47. Dinas Fawr, Four Mile Bridge—Mylonised gabbro with relics of diallage.
48. Yr Hendty, Four Mile Bridge—Talcose epidote schist.
49. Penryn Fadoc, Four Mile Bridge—Mylonised talcose epidote schist.

50. Tywyn Railway Cutting—Ditto, more altered (fig. 23).
51. South side of inlet, Four Mile Bridge—Serpentine derived from saxonite.
52. Valley, near Cruglas—Ophicalcite derived from lherzolite.
53. Cruglas—Ophicalcite from limestone.
54. Pwll Clai, north of Roscolyn—Talcose schist.
55. Llyn Trefwll—Cataclastic granite.
56. Llyn Trefwll—Diabase.
57. Llyn Trefwll—Slightly schistose diabase.
58. Llyn Trefwll—Diorite with fragment of granite.
59. Bottom of Gogarth—Medium-grained grit.
60. Flaggy beds at South Stack—Fine-grained rock, with foliation oblique to both bedding and cracks.
61. Slaty, Porth-da-farch—Medium-grained rock, mylonised.
62. Porth-y-crug—Fine-grained rock, with strain-slip cleavage, against a cylinder of grit (? a worm casting) (fig. 16).
63. Porth-y-crug—Medium-grained grit.
64. Porth-y-gwalch—Quartzite, showing fracture cleavage, zircons.
65. Roscolyn—Quartzite, showing fracture cleavage, zircons.
66. South of Roscolyn—Microspectral schist with fracture cleavage, rutiles (fig. 9).
67. Roscolyn slate—Confused microspectral schist with few fragments, some of mica, chlorite transverse in nests.
68. Green rock, north side of Borthwen—Epidote crystals in dark dust.
69. Gwalchmai Lowest, west of stream—Gneiss, with laminar orientation, and microcline, &c., in cracks (fig. 8).
70. West of Gwalchmai—Cataclastic gneiss.
71. Gwalchmai Turnpike—Coarse mica schist, with linear orientation.
72. Bodwrog Church—Gneiss with laminar orientation.
73. Road north of Pen-y-carnisiog—Gneiss with laminar orientation.
74. Porth-y-ly-wod Island—Coarse mica schist with linear orientation.
75. Porth-y-fawch—Fine mica schist with quincuncial orientation (fig. 5).
76. Porth Gwyfen, east side—Gneiss with few remaining fragments.
77. Llangwyfen—Fine mica schist with quincuncial orientation.
78. North of Llangwllog stream—Gneiss with laminar orientation, very little mica.
79. South of Llangwllog stream—Cataclastic gneiss.
80. Y Foel, Llanerchymedd—Sericitic gneiss.
81. Gorse Mill, South of Llanerchymedd—Decomposed gneiss with derivative mica (fig. 2).
82. By Llanfaelog Church—Fine felted mica.
83. East of Porth-ceryg-defaid—Fine cataclastic quartz-felspar mosaic.
84. Nearest gneiss, Porth-y-ly-wod—Cataclastic gneiss.
85. Between Ty Croes and Llanfaelog—Fine-grained, micaceous, with larger fragments.
86. Gwalchmai, between granites—Quartz-felspar mosaic.
87. North side of Llangwllog—Cataclastic quartz-felspar mosaic.
88. West of Bodorgan—Dislocated cataclastic rock.
89. Lump in ashy bed, Llancadwaladr—Coarse quartzose fragmental rock.
90. In gneiss, west side of Trecastle Bay—Large orientated calcite.
91. Bodwrog—Irregular large calcite.
92. Behind Druid Inn—Coarse mosaic limestone.
93. Railway Cutting, north of Llangwllog—Volcanic tuff, with mica of two generations, the first with inclusions.
94. South of Cerrig Ceinwen—Fragments of calcite and jasper in calcitic cement.
95. In limestone south of Cerrig Ceinwen—Jasper of small siliceous elements.
96. Quartz knob, Bethel, Bodorgan—Large rounded quartz fragments with needles in a polygonal quartz matrix.
97. Quartz knob, east of Llangefni—Various rounded fragments in pure quartz matrix.
98. Cerryg-ddwyffordd—Fine-grained rock.
99. Cerryg-ddwyffordd—Fragmental rock.
100. Just north of Llangefni—Fine-grained rock.
101. Further north of Llangefni—Dislocated and cataclastic.
102. Side of River Cefni—Fine-grained rock, spectrally polarised.

103. Chlorach Bach, Llanerchymedd—Fine-grained rock with infusion of calcite.
104. Trewyn, Bodafon—Fine-grained rock with abundant quincuncial mica.
105. Under southern hill, Bodafon—Showing elemental orientation.
106. By Bodafon Farm—Fine-grained micaceous rock with fragments.
107. Carnedd a Tre'r beidr, Bodafon—Fine-grained, with fragments elementally orientated.
108. Clegyr, Bodafon—Fine-grained rock.
109. Bodafon Hill—Quartzite of coarse groundmass elementally orientated.
110. West side of Bodafon—Fine felted mica.
111. Craig Fryr—Quartzite of coarse groundmass elementally orientated.
112. Llanfaelog—Chloritised granite.
113. Intrusion, west of Porth-y-ly-wod—Cataclastic granite or mortar structure.
114. Border of granite, near Pen-y-carnisiog—Glomeroporphyritic microgranitic felsite.
115. Gwalchmai—Cataclastic granite or mortar structure.
116. Near Craig-yr-allor—Chloritised granite.
117. Henblas, Llandrygarn—Clean granite.
118. Ynys Dodyn, south of Rhos Goch—Cataclastic granite, microspectral and with microcline in cracks only.
119. Tyn-y-Pwll, south of Llanerchymedd—Glomeroporphyritic microgranitic felsite.
120. Bryn-Twrog, south of Llanerchymedd—Cataclastic granite.
121. Yrynys Coed, Coedana—Cataclastic granite or mortar-structure.
122. Junction at Maengwyn, Coedana—Coarse granite with tourmaline, in dusty schist, with mica in cracks.
123. Tafarn-y-botel, Llanerchymedd—Gneissose granite, or granitoid gneiss.
124. Just north of Llecheyn-farwy—Plagioclastic rock.
125. First green band, west of Llangwfen—Mylonitic diabase.
126. Dinas Llwyd—Coarse fragmental rock.
127. South of Bodowen—Olivine diabase.
128. Craig-yr-allor—Foliated hornblende, plagioclase, and ilmenite.
129. Craig-yr-allor—Cataclastic (epi?) diorite.
130. Craig-yr-allor—(Epi?) diorite, formerly a dolerite.
131. Near Craig-yr-Allor—Foliated (epi?) diorite with abundant sphene.
132. Northern boss, Craig-yr-allor—Cataclastic diorite, now chlorite and calcite.
133. North of Llandrygarn—Coarse mica diorite with sphene.
134. West of Penterfyn, Rhos Goch—Coarse mica diorite with apatite and sphene.
135. Yrynys Coed, Coedana—Cataclastic gneiss with chlorite.
136. South-west of Plas Llanfihangel—(Epi?) diorite.
137. East of Plas Llanfihangel—Complex of minerals, including pyroxene and rutile.
138. Gwalchmai—Spicular plagioclase in magnetite
139. South of Traeth Dulas—Somewhat cataclastic white granite.
140. South of Traeth Dulas—Quartz-felspar mosaic.
141. South of Traeth Dulas—Gneiss with confused orientation.
142. South of Traeth Dulas—Fine mica schist, quincuncial orientation.
143. Newborough Warren, Bryn Gorsddu—Fragments with mica infilling.
144. South of Hafodty—Fine mica schist with elemental orientation.
145. Hafodty, south of Llangaffo—Laminated rock, epidote, surrounded by chlorite.
146. Bodowyr, valley of River Braint—Fine mica schist with elemental orientation, vermiculite.
147. South of Bodlew, River Braint (E.)—Fine felted mica (fig. 11).
148. South of Bodlew, River Braint (W.)—Mosaic rock with microspectral crape structure (fig. 15).
149. Ty Mawr, south of Llandaniel—Crape structure in quartz vein only.
150. Llangaffo Cutting—Coarse mica schist, straight linear mica (fig. 6).
151. Main line, south of Holland Arms—Cataclastic coarse mica-schist, speckled felspar (fig. 1).
152. Quartzose lump, Berw Ycha—Coarse mica schist with linear orientation, and fragments.
153. Farm, south of Holland Arms—Coarse mica schist.

154. South of Plas Berw—Gneiss with laminar orientation.
155. Tros-y-gors, near Menai Bridge—Elemental orientation (fig. 7).
156. North of Union Inn, Holyhead Road—Coarse mica schist with linear orientation and garnets.
157. Cefn Du, Gaerwen—Microspectral and crape structure (fig. 14).
158. East of Gaerwen Windmill—Coarse microspectral mica schist.
159. Y-graig, Gaerwen—Gneiss microspectrally polarised at edges of elements.
160. North end of 'gneiss,' Holland Arms—Microspectral, vermiculite.
161. Gors Llwyd, near Llaniestyn—Microspectrally polarised at edges of fragments.
162. Minffordd Waste—Fragmentary with chloritic base.
163. Over Tyn-y-Mynydd, Mynydd Llwyddiart—Laminated schist.
164. South of Newborough—Variolitic hornblende epidote schist.
165. Side of River Braint, Bryn Gwyn—Slate-like mylonised hornblende epidote schist (fig. 24).
166. Intrusive, in Llangaffo Cutting—Fine-grained hornblende epidote rock.
167. Tyn-drain, River Braint—Glaucophane and epidote.
168. Anglesey Monument (longitudinal)—Felted glaucophane and epidote schist.
169. Anglesey Monument (transverse)—Felted glaucophane and epidote schist.
170. Carnen Goch, near Llanfair—Mylonised glaucophane epidote schist.
171. Road to Castellor (S.)—Glaucophane and epidote schist with tourmaline.
172. Road to Castellor (N.)—Variolitic glaucophane epidote schist.
173. Gaerwen Windmill—Squeezed hornblende and epidote in bands.
174. Behind Gaerwen Windmill—Orientated fine-grained hornblende and epidote.
175. North of Holland Arms—(Epi ?) diorite with sphene.
176. North of Holland Arms—Contorted hornblende epidote schist.
177. South of Y-graig—Fine-grained hornblende and epidote schist with rutiles.
178. North end of wood, Y-graig—Decomposed epidote and hornblende in bands.
179. North of Y-graig—Cataclastic diorite.
180. Ysgubor Llwyd, Gaerwen—Coarse (epi ?) diorite.
181. North of Holland Arms—Abundant hornblende with epidote and sphene.
182. North end of 'gneiss,' Holland Arms—Mylonitic diorite.
183. Llangefni to Beaumaris—Cataclastic diorite.
184. South of Pentreath—Powdered diorite.
185. West of Tyn Lon—Cracked fine-grained hornblende and epidote.
186. Summit of Mynydd Llwyddiart—Cracked fine-grained hornblende and epidote.
187. Cadnant Vale, Menai Bridge—Fine-grained rock.
188. Ty Gwyn, Menai Bridge—Fine-grained rock with fragments, microcline.
189. Bryn Minceg, North of Llandegfan—Many fragments in chloritic groundmass.
190. North-east end of Malldraeth Marsh—Fine mylonitic slate.
191. South of Beaumaris—Fine epidote dust rock.
192. Garth Ferry to Beaumaris—Fine decomposed epidote in groundmass of chlorite.
193. Pen-y-Parc, Beaumaris—Mylonitic grit (fig. 17).
194. North of Garth Ferry—Entirely cataclastic.
195. Ty Garw, Beaumaris—Fine-grained rock.
196. Clawd-y-Parc, north of Llandegfan—Mylonitic crystalline fine-grained rock.
197. Gallows Point, Beaumaris—Fragments in quartzose and calcitic mass.
198. Llyn Bodgolched, north of Beaumaris—Fine-grained rock.
199. Tyddyn, north of Beaumaris—Fine-grained rock, full of mylonitic lines.
200. Near Coedmawr, Llanfaes—Mylonised fine-grained rock with fragments.
201. Penrhos, near Wugan—Medium-grained rock.
202. Rhyd Eilian—Coarse mosaic limestone.
203. Quartz knob, Pen-y-Parc, Beaumaris—Various rounded fragments, mostly quartz, in pure quartz matrix.
204. Gwladys—Isolated rhombohedral calcite in dusty matrix.
205. Intrusive, Gwladys—Fine mosaic of calcite and quartz.
206. Spheroidal rock, Gwladys—Spicular plagioclase.
207. Variolitic, Gwladys—Spicular with imperfect spherules and varioles (fig. 22).
208. Gwladys—Fine-grained rock.

- 209. Junction near Bwlch, Llanddona—Fine mica schist.
- 210. Llanflewlin—Fine-grained rock with few fragments, and confused orientation.
- 211. Mynydd Mechell—Fine mica schist with quincuncial orientation.
- 212. Mynydd Mechell—Fine quincuncial orientation, parallel to bedding.
- 213. Llanrhwydrus to Camlyn—Fine-grained chloritic rock with fragments.
- 214. Port Unal, Camlyn—Quartz elements with sericitic boundaries, zircon.
- 215. Intrusive, Port Unal—Fine mosaic limestone with quartzose cracks.
- 216. West of Cemmaes—Fine and coarse mixed; tension areas.
- 217. Llanbadrig—Oolitic limestone (fig. 19).
- 218. Llanlliana—Fine mosaic limestone.
- 219. West of Llanfechell—Fine-grained chloritic rock with fragments.
- 220. Bodewryd Turret—Fine abundant mica quincuncially orientated.
- 221. Llechog Ucha, west of Amlwch—Mylonised fine-grained rock with tension areas.
- 222. Pengorphwyfsa, east of Amlwch—Fine-grained rock with fragments; tension areas.
- 223. Llaneilian, east of Amlwch—Plagioclase well preserved.
- 224. Point Ælianus, east of Amlwch—Plagioclase well preserved.
- 225. Dyke, east of Mynydd Mechell—Macrofelsite with epidote nests (fig. 20).
- 226. Dyke, east of Mynydd Mechell—Spherulitic microgranite.
- 227. Spheroidal boss, west of Amlwch—Spicular macrofelsite with idiomorphic epidote.
- 228. Hafod Oren, south of Amlwch—Pseudo-spherulitic granophyr (fig. 21).
- 229. Amlwch to Parys Mountain—Diabase with epidote and leucoxene.
- 230. Boss at Tygorphwyfsa—Microgranite.
- 231. Quartz mass, west of Bull Bay—Quartz elements with sericitic boundaries.
- 232. Quartz knob, south-west of Parys Mountain—Pure quartz of polygonal structure (fig. 18).
- 233. North side of Porth Lygan—Typical granite.
- 234. Porth Lygan district—Granular sericitic felsite.
- 235. Porth Lygan—Non-quartzose, slightly foliated micaceous tuff.
- 236. Porth Lygan—Mylonised micaceous tuff.
- 237. Opposite island, Porth Lygan—Quartzo-felspathic micaceous tuff.
- 238. Abertywedog—Garnet, quartz, and diallage (?).
- 239. Abertywedog—Micaceous tuff with altered garnets.
- 240. Abertywedog—Quartzose non-micaceous tuff.
- 241. Trwyn, near Abertywedog—Decomposed plagioclase, two pyroxenes and sphene. (Paraboloid.)
- 242. Llanwenllwyfo, south end—Quartzose micaceous tuff.
- 243. Rhos Manarch, inland—Dolerite.
- 244. Pen-yr-Allt, west of Porth Lygan—Granite with altered garnets.
- 245. Ty Newydd, north of Nebo—Gneiss with brown mica.
- 246. Penrhynglas, Llanwenllwyfo—Micaceous tuff with garnet groundmass.
- 247. Nebo, south of Road—Felspathic micaceous tuff.
- 248. In micaceous rock, Nebo—Calcite, plagioclase, and sphene.
- 249. Outer ridge, east of Parys Mountain—Mica-diorite with apatite, &c.
- 250. East of Parys Mountain—Grey gneiss.
- 251. East of Parys Mountain—Brown-mica-diorite with sphene, apatite, &c.
- 252. East of Parys Mountain—Plagioclastic rock with mica in cracks.

23. „ 50. Talcose schist derived from gabbro. The dark patches are epidote, the lightest talc.
24. „ 165. Slaty diorite. The dark spots are epidote, the lightly shaded hornblende or chlorite.

Report of the Committee, consisting of Mr. THISELTON-DYER (Secretary), Mr. CARRUTHERS, Mr. BALL, Professor OLIVER, and Mr. FORBES, appointed for the purpose of continuing the preparation of a Report on our present knowledge of the Flora of China.

THE further grant made by the Association has assisted the Committee in advancing rapidly with the work, the importance of which is generally acknowledged by botanists. It is based, in the first instance, on the manuscript collections made by Mr. Forbes, as the result of many years' work. These collections have been placed by him, with great liberality, in the hands of the Committee. With these collections are worked up the additional material derived from an examination of the herbaria of Kew and the British Museum (including Dr. Hance's extensive Chinese herbarium acquired last year by the trustees of the latter institution). The Committee pay the expense of drawing up the successive portions of the report from these materials, and also the cost of setting up in type and printing 100 copies of each part. These are distributed to everyone in China whose co-operation there is any likelihood of enlisting in obtaining further collections which would throw light upon its flora. The result has been to excite an amount of interest which could hardly have been anticipated. The Committee have in particular to express the obligations they are under to various members of the Inland China Mission, of the Chinese Imperial Maritime Customs, and of the British Diplomatic Service in China. The Committee have been further aided by grants from the Government Grant Committee of the Royal Society.

In order to make the result of their labours of permanent usefulness to the scientific world, the Committee have allowed the Linnean Society to print from the type, at its own expense, copies for distribution to its fellows. The Council of the Society further pay the expense of two plates for each part.

During the past year three more numbers have appeared, and the grant made by the Association about covers the expense of setting these up in type. This brings the Report down to the beginning of *Compositae*,

and Mr. Hemsley has since made rapid progress with this order, the discussion of which will occupy about 100 pages.

Dr. A. Henry has presented further large collections to Kew, with a view to their being used for the Report. These have yielded numerous novelties—the most remarkable of which have been published in Hooker's 'Icones Plantarum.' One of the most important is a new genus (*Trapella*, Oliver), a peculiar aquatic type, which is the subject of an elaborate memoir by Dr. F. Oliver in 'The Annals of Botany.'

Another important collection has been received from the Rev. E. Faber from the western province of Szechuen, and chiefly on Mount Omei, which has an altitude of 11,000 feet. These contain an element of Indian species, intermixed with others which are identical with those sent by Dr. Henry from the neighbourhood of Hupeh. There are also many new species; amongst them *Nertera sinensis*, Hemsl., a new species of a genus whose head-quarters are in the Southern Hemisphere. The ferns contain twelve new species, besides an equal number of others not previously known, from China. Scarcely any of the plants, however, are the same as those from the mountainous regions of Yunnan. Other small collections have also been received.

As an interesting sample of the flora of China, attention may be drawn to the *Caprifoliaceæ*, published in the last part of the Index. There are eleven genera, one of which is new, and seventy-seven species, of which fifteen are new. *Viburnum* and *Lonicera* number respectively twenty-seven and thirty-four species. This is by far the greatest concentration of the order.

The Committee recommend their reappointment, and that a further sum of 100*l.* be placed at their disposal.

Second Report of the Committee, consisting of Professor FOSTER, Professor BAYLEY BALFOUR, Mr. THISELTON-DYER, Dr. TRIMEN, Professor MARSHALL WARD, Mr. CARRUTHERS, Professor HARTOG, and Professor BOWER (Secretary), appointed for the purpose of taking steps for the establishment of a Botanical Station at Peradeniya, Ceylon.

THE Committee report that no part of the grant has as yet been expended. Though several botanists have expressed themselves as desirous of going to Peradeniya, in the end no one was able technically to accept the situation during last year. The Committee now learn that Mr. Potter, of St. Peter's College, Cambridge, has decided to go out during the ensuing winter. The grant of 50*l.* has accordingly been drawn, and the Secretary is in communication with Dr. Trimen, Director of the Royal Gardens, Peradeniya, as to the apparatus which should be purchased with that sum.

The Committee, in presenting this as an interim report, request that they may be reappointed for the ensuing year, but do not ask for any further grant at present.

Eighth Report of the Committee, consisting of Mr. R. ETHERIDGE, Mr. THOMAS GRAY, and Professor JOHN MILNE (Secretary), appointed for the purpose of investigating the Earthquake and Volcanic Phenomena of Japan. (Drawn up by the Secretary.)

EARTHQUAKES IN 1886.

In my fourth report to the British Association (1884) I gave the results obtained from the observation of 387 earthquakes which had occurred between October 1881 and October 1883 in North Japan. The valuable nature of these results led the Meteorological Department of this country to establish post-card stations throughout the empire, with the object of making similar but more extended observations. An epitome of the results obtained during 1885 was given in my sixth report to the British Association, and through the kindness of Mr. Aria Ikunosake, the Director of the Meteorological Department, I am now enabled to give a summary of the observations made in 1886. Here and there these are supplemented with my own remarks.

(a) *Frequency of Earthquakes.*—During 1886 the number of earthquakes recorded in Japan was 472, which is equivalent to an average of 1·3 per day. In 1885 there were 482. The greatest number of shakings felt in any one province was in Shimotsake, 30 or 40 miles north of Tokio, where sixty-one shakings were recorded. Some of the provinces on the western side of the empire do not appear to have felt any shakings.

(b) *Distribution of Seismic Energy.*—Speaking generally, the eastern part of Japan was greatly shaken, while to the west of the mountains, forming the backbone of the country, disturbances were rare. The general distribution of seismic energy therefore remains as it has been in previous years. If, however, we make a detailed examination of this distribution, a few exceptions to the observations of 1885 may be discovered, one of which was the great increase in the earthquakes felt in Shinano, an inland province 60 miles east of Tokio, and the other in the province of Echigo, about 100 miles north of Tokio. In Shinano the number of shocks increased from 9 to 19, while in Echigo they increased from 3 to 31. In other provinces a decrease was observed.

It is extremely interesting to observe that Echigo and Shinano lie along a N.N.W. line, which, so far as the strike of rocks is concerned, divides the main island of Japan into two halves. Along this line, and to the north and east of it, there are many volcanoes, while to the west and south there are practically none. The strongest shock was the Echigo-Shinano shock of July 25, which caused considerable damage to buildings, walls, bridges, &c.

The districts most shaken were the east coast from Tokio northwards, the north-east corner of Yezo, the southern extremity of the Kii peninsula, and the southern part of Kinshin.

The positions of the origins of the shocks which have been recorded were approximately as follows :—

	Originating beneath the sea or on the coast	Originating beneath the land	Total
Total number	228	244	472
Shocks shaking a large area .	15	11	26
Shocks shaking a moderate area .	50	70	120
Shocks shaking a small area .	163	163	326
Total	228	244	472

In many respects the relationship of earthquakes to volcanoes was the same as in the previous years; as, for example, in Central Japan, where there are many volcanoes and many earthquakes, the earthquakes have not originated from the volcanoes. Again in the Kii peninsula, where there are no volcanoes, earthquakes were frequent. In other districts there are many volcanoes and comparatively few earthquakes.

(c) *Distribution of Earthquakes in Time.*—The number of earthquakes which occurred in different months and seasons will be seen from the following table:—

January	38	} Spring, 126.	July	36	} Autumn, 123.
February	39		August	46	
March	49		September	41	
April	38		October	33	
May	58	} Summer, 126.	November	22	} Winter, 97.
June	30		December	42	
Cold months, 223.			Hot months, 249.		

The distribution of earthquakes, according to the hours of the day, during 1885 and 1886 is shown in the following table:—

Time	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Total
0 to 1 A.M.	0	4	2	3	2	6	4	3	0	1	4	4	33
1 to 2 "	2	7	3	0	2	6	3	0	4	6	2	1	36
2 to 3 "	4	3	7	5	8	4	5	11	11	1	3	3	65
3 to 4 "	4	4	3	4	10	0	4	3	5	3	4	4	48
4 to 5 "	1	4	0	3	6	4	1	2	3	1	1	1	27

9 to 10 "	4	4	3	5	2	8	2	2	3	4	1	1	39
10 to 11 "	6	0	2	4	0	2	1	1	2	2	2	3	25
11 to 12 "	2	3	3	4	6	4	4	2	4	3	3	6	44
0 to 1 P.M.	2	2	1	1	3	1	3	2	6	3	2	2	28
1 to 2 "	2	4	4	3	10	3	2	3	4	6	5	3	49
2 to 3 "	6	2	9	3	5	3	6	4	3	3	3	4	51
3 to 4 "	1	3	1	5	4	1	2	5	4	2	2	3	33
4 to 5 "	2	2	6	2	5	3	2	2	1	1	1	2	29
5 to 6 "	3	8	3	2	3	5	2	0	2	0	0	1	29
6 to 7 "	2	2	3	3	4	3	3	3	6	4	2	4	39
7 to 8 "	3	5	2	4	2	3	3	4	2	5	3	3	39
8 to 9 "	1	2	3	4	6	2	4	4	4	5	8	7	50
9 to 10 "	2	2	4	1	5	3	2	4	6	3	5	6	43
10 to 11 "	6	9	7	2	3	5	1	4	0	6	4	9	56
11 to 12 "	5	6	3	2	2	4	1	7	2	3	4	5	44
Total .	71	83	86	75	109	76	68	76	86	74	69	82	955

The mean number of earthquakes which occurred per hour is approximately 40. Calling the time from 6 P.M. to 6 A.M. night, and the remaining hours out of the twenty-four, day, we find that 86 more earthquakes were recorded during the night than during the day. The probable explanation of this observation is, that during the night persons are more favourably situated for the observation of small disturbances than they are during the day. During the day, when a person is engaged in active work, especially if out of doors, it has often been observed that earthquakes are passed by unnoticed, while at night, if not sleeping too soundly, the slightest tremor may be recorded.

Under the heading 'Seismic Survey of Tokio' reference is again made to this subject.

(d) *Area shaken by Earthquakes in 1885 and 1886.*—Inasmuch as there are many reasons for believing that the depth at which an earthquake originates is usually incomparable with the radius of the area shaken, the area shaken may be taken as a very fair estimate of the intensity of any given disturbance. The following table gives the sum of the areas shaken per month and the mean area per shock. The unit is one square ri, or 5.9553 square miles.

	TOTAL AREA			MEAN AREA PER SHOCK		
	1885	1886	Average	1885	1886	Average
	sq. ri	sq. ri	sq. ri	sq. ri	sq. ri	sq. ri
January . . .	10,020	3,240	6,630	370	80	195
February . . .	16,980	5,550	11,265	390	140	265
March . . .	7,320	4,810	6,065	200	100	150
April . . .	4,750	12,480	8,615	130	330	230
May . . .	10,380	15,380	12,880	200	260	230
June . . .	15,890	5,080	10,485	370	170	270
July . . .	9,170	10,490	9,830	290	290	290
August . . .	6,060	10,820	8,440	210	230	220
September . . .	4,570	9,500	12,035	320	230	275
October . . .	21,340	3,860	12,600	520	120	320
November . . .	4,120	2,480	3,300	80	110	90
December . . .	1,170	8,360	10,030	290	200	245
Total . . .	111,770	92,050	112,175	3,370	2,260	2,780
Average . . .	11,025	7,671	9,348	276	189	232

The total area, 92,050 square ri, shaken in 1886 is 3.8 times the area of the empire, which, exclusive of small islands and Loo Choo, is 24,352 square ri. There were only 66 earthquakes which exceeded the mean value of 189 square ri.

From the following table we see that the greater intensity of 1885 was due to the fact that in that year there were more shocks of large extension than in 1886, when the majority of shocks (349) were local in their character. It also gives the number of earthquakes of different intensities, reckoned as areas shaken, felt during different months.

Area	Year	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Total	Mean

(e) *Special Earthquakes.*—On April 13, at 5.50 A.M., a strong earthquake, extending over 4,980 ri, was felt in the north part of the main island. It commenced with a rumbling, and the shaking lasted for three minutes. It does not appear to have been felt in Yezo, from which the shaken districts are only separated by straits, which at one point are only 10 miles in width. At Nemuro, at the north-eastern corner of Yezo, a

slight shock was felt; while, to the west of the centre of this island, the Tarumai volcano burst into eruption. These two earthquakes and the volcanic eruption all took place within at most a few minutes of each other.

On July 23, at 1 A.M., the provinces of Shinano and Echigo were violently shaken by a disturbance extending over 2,990 square ri. This is a district where in the previous year, although there are volcanoes in the vicinity, there had not been any earthquakes. During the next five hours this severe shock was followed by 23 minor disturbances. Here and there cliffs fell down, roads and bridges were damaged, houses upset or tilted, stone walls thrown over, and much damage done to roofs, furniture, and especially to the contents of stores. At the same time a small shock was felt more than 100 miles to the south-east in the province of Mino.

On August 10, at 9.30 P.M., a strong shock originated in the Bungo Channel between the islands of Shikoka and Kiushiu, which extended a considerable distance inland. It was succeeded by two or three other disturbances. Shocks have often been noticed on the shores of the Bungo Channel, but this one is remarkable as being the most severe which has occurred in that locality for many years.

EARTHQUAKES RECORDED IN TOKIO.

The systematic observations of earthquakes by the Meteorological Department in Tokio commenced in 1875. From that time up to 1885 Palmieri's instruments were employed. From 1885 up to the present time a Gray-Milne seismograph has been the standard instrument and Palmieri's instruments are no longer employed. From 1876 to 1882 the observations were made in a district known as Avicho; since then, owing to the removal of the Central Meteorological Station, the observations have been made at Hon Maru, in the castle grounds in the centre of the city. From 1876 to 1886 inclusive 658 earthquakes were recorded. The following analyses of these disturbances are of interest, as they refer to a particular seismic area, the earthquakes felt in which, for the most part, probably come from one or two particular origins, whereas the earthquakes referred to in previous tables originated from a large number of different centres distributed throughout the empire.

(a) *Distribution according to Time.*—The following table gives the distribution of earthquakes according to months in different years:—

Year	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Total	Average
1876	3	4	6	11	5	3	3	5	3	3	4	6	56	5
1877	4	5	6	5	8	6	6	4	1	8	6	9	71	6
1878	3	8	7	2	5	4	4	1	2	4	6	4	50	4
1879	6	7	14	0	9	4	3	4	1	7	6	9	70	6
1880	9	9	6	6	2	9	8	4	1	3	10	10	77	6
1881	13	8	8	8	4	3	3	3	2	3	3	8	66	5
1882	4	7	15	6	3	2	2	1	1	4	1	0	46	4
1883	6	0	3	3	6	2	3	1	0	1	3	4	32	3
1884	5	2	8	2	9	4	1	4	2	8	8	15	68	6
1885	7	9	8	4	3	6	0	3	8	10	3	7	68	6
1886	3	3	3	2	8	4	2	8	7	4	2	8	54	4
Total	63	62	84	49	62	50	35	38	28	55	52	80	658	54.8
Average	6	5	8	5	6	5	3	3	2	5	5	7	60	5

Considering March, April, and May as Spring, and the following three groups of three months respectively, Summer, Autumn, and Winter, the distribution of shocks according to these seasons has been as follows :—

Year	Spring	Summer	Autumn	Winter	Average
1876	22	11	10	13	14
1877	19	19	15	18	18
1878	14	9	12	15	25
1879	23	11	14	22	17
1880	14	21	14	28	19
1881	20	9	8	29	16
1882	24	5	6	11	11
1883	12	6	4	10	8
1884	19	9	18	22	17
1885	15	9	21	23	17
1886	13	14	13	14	13
Average	18	11	12	19	15

The distribution of earthquakes in relation to the cold months and warm months has been as follows :—

Year	Cold	Warm	Average
1876	26	30	28
1877	38	33	35
1878	32	18	25
1879	49	21	35
1880	47	30	39
1881	43	23	33
1882	31	15	23
1883	17	15	16
1884	46	22	34
1885	44	24	34
1886	23	31	27
Average	36	24	30

The following table gives the distribution of 658 earthquakes according to hours :—

Time		Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Total
A.M.	0 to 1	4	4	2	2	1	2	2	1	2	2	0	6	28

Total . . .	63	62	84	49	62	50	35	38	28	55	52	80	658

As the above records were obtained from instruments, any results they may yield are probably more trustworthy than those obtained from any tables which have been previously published. The greatest number of earthquakes have occurred between 8 and 9 P.M. and 9 and 10 A.M., while the fewest have been recorded between 11 and 12 A.M. and 8 and 9 A.M.

Between 6 P.M. and 6 A.M. 351 earthquakes were recorded, while during the day, that is from 6 A.M. to 6 P.M., 307 were noted.

The hours at which earthquakes have been most frequent in successive months are in nearly all cases quite different.

(b) *Severe Earthquakes.*—The following are the most severe earthquakes felt in Tokio in successive years:—

Year	Month and Day	Time	Range of Motion, &c.
		H. M. S.	
1876	Jan. 20	8 44 30 P.M.	21°
1877	July 22	4 49 17 P.M.	11°
1878	Feb. 23	6 3 45 A.M.	19° 20'
1879	Dec. 3	7 8 0 A.M.	18° 30'
1880	Feb. 22	0 50 19 A.M.	78°
1881	June 18	10 25 0 A.M.	8° 30'
1882	March 11	7 50 54 P.M.	11° 20'
1883	June 10	10 15 0 P.M.	18° 20'
1884	Oct. 15	4 21 54 A.M.	95° 10'
1885	March 20	1 1 13 P.M.	22°
1886	May 8	10 14 0 P.M.	2.8 mm in .4 sec.

As Palmieri's instrument is only graduated to 25°, two of the above measurements were estimated. On October 15, 1884, a few walls were cracked in Tokio, several brick chimneys fell, tiles were dislodged, a few storehouses fell, and much furniture was damaged. On February 22, 1880, there was similar damage in Tokio.

The following is an abstract of notes on these and other earthquakes, which I drew up for the consideration of a committee now sitting in Tokio to consider the question of construction in earthquake countries.

*February 22, 1880.*¹—This earthquake created considerable destruction in Yokohama. At that place very many brick chimneys fell. At many houses the tiles on the roof were shaken loose, while several were

¹ *Trans. Seis. Soc.* vol. i., part 2.

completely unroofed, one of which was a strong brick building. The main timbers in certain roofs were broken. Grave-stones were rotated. Many windows were broken, and bodies like the tops of stone lanterns, corner stones of chimneys, &c., were projected.

In Tokio a few chimneys fell, tiles were dislodged from the eaves of buildings, and portions of a few walls were cracked or shattered. In some instances these latter fell.

In Yokohama the range of horizontal motion appears to have been from 15 millimetres ($\frac{5}{8}$ inch) to a maximum of 50 millimetres (3 inches). Calculations of maximum velocity were made, but as the data on which they were founded do not appear to have been satisfactory they are here omitted.

In Tokio the amplitude (range of motion) observed at Surugadai was 21 millimetres. Assuming the larger vibrations to have been performed at the rate of one per second, this would indicate a maximum velocity of 60 millimetres per second, and a maximum acceleration of 360 millimetres per second. With a period of two seconds, which is probably a more correct assumption, the above quantities would respectively become 30 and 90 millimetres.

October 15, 1884.—One or two chimneys fell in Tokio, plaster fell from ceilings, and several brick walls were cracked. In Tokio, at Hitotsubashi-soto the greatest horizontal motion observed was 43 millimetres and the period two seconds. This indicates a maximum velocity of 68 millimetres and a maximum acceleration of 210 millimetres.

January 15, 1887.¹—This disturbance originated about 35 miles to the south-west of Tokio. Near to its origin it destroyed many *kura* (fire-proof storehouses built of wood, with a clay covering and a heavy roof of tiles), and opened fissures in the ground. In Yokohama, say ten miles from the origin, it destroyed many chimneys and slightly shattered several buildings. In Tokio a few brick walls were slightly cracked.

In Yokohama a horizontal motion of 35 millimetres was recorded.

In Tokio the following observations were made:—

—	Range of motion in millimetres	Period in seconds	Maximum velocity	Maximum acceleration	Vertical motion	Period of vertical motion in second
Hitotsubashi . . .	21	2.5	26	66	1.8	0.9
Hongo	7.2	2.2	12	36	1.3	1.0
Chirikioku	19.2	2.3	24	64	5.5	0.8

Hongo and the Chirikioku (Imperial Meteorological Observatory) are situated on moderately high ground, which is dry and hard. At Hitotsubashi, which is low, the ground is damp and soft.

The above measurements of range of motion and period were made on solid foundations. The range of motion at the top of a building would be greater while the period might be less. It seems from these observations that when there is an earth-movement of about 18 millimetres ($\frac{3}{4}$ inch) or over, it is likely that the period will be sufficiently short to result in some form of destruction.

Earthquakes of this description, Professor Sekiya observes, occur in Japan about once a year, and near to Tokio every few years.

¹ *Trans. Seis. Soc.* vol. ix.

(c) *Direction of Motion in Earthquakes.*—The following table shows the principal direction of movement of earthquakes as recorded in Tokio :—

Direction	PALMIERI												GRAY-MILNE	Total
	At Avicho								At Castle					
	1876	1877	1878	1879	1880	1881	1882	Total	1883	1884	1885	Total		
N.-S.	—	—	—	—	—	—	—	—	5	6	16	27	8	35
N.N.E.-S.S.W.	—	3	3	15	20	1	1	43	—	—	—	—	2	45
N.E.-S.W.	—	—	—	—	—	—	—	—	5	10	6	21	—	24
E.N.E.-W.S.W	8	15	3	10	1	3	12	52	—	—	—	—	2	54
E.-W.	—	—	—	—	—	—	—	—	8	25	7	40	14	54
E.S.E.-W.N.W	12	12	22	9	7	26	3	91	—	—	—	—	5	96
S.E.-N.W.	—	—	—	—	—	—	—	—	3	5	4	12	13	25
S.S.E.-N.N.W.	—	4	1	11	24	7	14	61	—	—	—	—	3	64
Uncertain	38	40	21	30	32	32	19	212	12	25	38	75	4	291
Total . .	58	74	50	75	84	69	49	459	33	71	71	175	54	688

When Palmieri's instrument was removed to the castle its orientation was changed to N.S., E.W. The above table shows that the principal direction of movement in Tokio is between E.-W. and S.E.-N.W., a fact which is of considerable importance to builders.

(d) *Earthquakes and Atmospheric Pressure.*—The following table shows the number of earthquakes which occurred between 1878 and 1886, during different months, with the barometer at different heights. The barometric readings are in millimetres :—

Barometer in mm.	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Total
745	1	—	—	—	—	1	—	—	—	—	—	—	2

771	2	—	4	3	—	—	—	—	—	1	—	—	10
772	—	—	1	1	—	—	—	—	—	2	2	3	9
773	—	—	—	—	—	—	—	—	—	2	—	—	2
774	2	—	—	—	—	—	—	—	—	—	—	1	3
755	—	1	—	—	—	—	—	—	—	—	1	—	2
Total .	56	53	72	33	49	38	26	29	24	44	41	65	530

The ratio of the number of earthquakes which have occurred when the barometer has been below the average pressure, to the number when the barometer has been above the average pressure, is as 56 : 44.

The number of earthquakes which have occurred in each month when the atmospheric pressure has been above the average, and the number which have occurred when it has been below the average, are given in the following table:—

—	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Total
Above average pressure .	23	15	43	17	28	17	6	16	17	21	19	34	256
Below average pressure .	33	38	29	16	21	21	20	13	7	23	23	31	275
Total .	56	53	72	33	49	38	26	29	24	44	42	65	531

The next table gives the number of earthquakes which have occurred when the barometer has been rising, when it has been falling, and when it was steady:—

—	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Total
Rising .	21	19	19	12	15	9	9	15	6	19	12	14	170
Falling .	18	20	24	12	11	7	6	1	5	13	13	26	153
Steady .	20	14	29	9	23	22	11	13	13	12	17	25	208
Total .	56	53	72	33	49	38	26	29	24	44	42	65	531

Earthquakes therefore appear to be most frequent when the barometer has been steady, less when it has been rising, and least when it has been falling.

(e) *Earthquakes and Temperature.*—The following table gives the number of earthquakes felt between 1877 and 1886, when the thermometer has shown different temperatures:—

Temperature	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Total

Total .	60	58	78	38	57	47	32	33	25	52	48	74	602

The average temperature in Tokio is 14° C.

The following table shows the number of earthquakes which have occurred during each month when the temperature has been above or below the average temperature of the month :—

—	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Total
Above average temperature.	25	36	36	19	22	31	19	18	11	20	20	26	283
Below average temperature.	35	22	42	19	35	16	13	15	14	32	28	48	319
Total .	60	58	78	38	57	47	32	33	25	52	48	74	602

The number of earthquakes which have been recorded when the temperature has been below the average are to the number which have

been recorded when the temperature has been above the average as 60 : 40.

The number of earthquakes which have occurred each month when the temperature has been rising, falling, or steady are given in the following table:—

—	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sep.	Oct.	Nov.	Dec.	Total
Rising . . .	24	19	24	10	21	19	6	10	5	18	15	34	205
Falling . . .	31	29	39	18	31	22	22	21	15	27	31	35	321
Steady . . .	5	10	15	10	5	6	4	2	5	7	2	5	76
Total . . .	60	58	78	38	57	47	32	33	25	52	48	74	602

Earthquakes have therefore been more numerous when the temperature is falling. To connect these observations with those relating to barometric pressure, it may be well to remember that generally a low temperature accompanies a high barometric pressure, and a high temperature a low barometric pressure.

These latter results respecting earthquakes and fluctuations of atmospheric pressure and temperature are similar to results obtained by the analyses of more meagre data which the Meteorological Department very kindly placed at my disposal some years ago. As I did not consider that the results were of sufficient importance for publication, until now no special reference has been made to them. The belief that there is an immediate connection between earthquakes and atmospheric conditions is, however, very general, and it is for the purpose of showing how little foundation there is for such a belief that I have been led to incorporate the previous analyses in the present report. The facts which have been recorded may also be of value to investigators who wish to carry out analyses on other lines.

EARTH-TREMORS.

In the report to the British Association for 1887 I gave an account of observations made with an automatic tromometer of tremors which had been observed between January 13, 1885, and May 14, 1886. Details of these observations may be found in 'Trans. Seis. Soc.' vol. xi. p. 1-78. The records referred to in the present note were obtained between December 22, 1886, and February 1888.

Results of Analysis.—From a general inspection of the tri-daily weather maps, it is quite clear that when little or no wind is indicated, or when the isobars are few, no tremors have been recorded; while, on the contrary, when the wind is strong at many stations in Central Japan, and when the isobars occur in close proximity, tremors are almost always recorded. On the Japanese maps the isobars are drawn at intervals of five millimetres of pressure. On the Italian maps, when the intervals are only one millimetre, the relationship between tremors and the frequency of isobars, which, when they are numerous, indicates a steep gradient, is even more marked than it appears to be in Japan. On the Italian maps, which are published under the direction of Professor M. S. de Rossi, the state of the wind is not indicated, but it may be inferred that when the gradients over the Italian peninsula are steep, wind is blowing somewhere in the peninsula, 1888.

and therefore in Italy as in Japan tremors are accompanied by wind, although the wind may not be blowing at some particular place where the tremors are observed. Certainly tremors often occur with a low barometer, but the greater frequency of tremors apparently happens when the gradient is steep, no matter whether the barometer is high or whether it is low, and cases may therefore be observed of low barometer unaccompanied by tremors. Observations like these have inclined me to the opinion that tremors are more closely connected with wind than with barometric pressure. An examination of the observations which have been made shows :—

1. That there are 80 cases of well-pronounced tremors having occurred with strong winds blowing in Central Japan. In several instances tremors were observed in Tokio some hours ahead of the wind, which was blowing heavily to the S.W., and travelling up the country towards Tokio. By Central Japan is meant all the country within 200 or 300 miles of Tokio.

2. There have been 40 cases of strong wind and no tremors. In 34 of these cases the wind has been local or of short duration ; that is to say, it was only observed in Tokio, or it was only observed at one of the tri-daily observations. In the remaining six cases, if tremors are the result of wind they ought to have been observed.

3. With no wind and no tremors there are 79 cases.

4. With *no* wind and *small* tremors there are 63 cases. In 39 of these cases the record on one band of paper showed no tremors, and therefore these 39 cases might have been classified in the preceding group. On the other band tremors were barely visible. In 8 of the remaining 26 cases the tremors observed were immediately in advance of a heavy wind, or were tremors continuing after a heavy wind had passed, at which time tremors had been well pronounced. There are therefore only 18 cases (26–8) where tremors can be said to have occurred where there was no wind, and these tremors were slight. The above results may be tabulated as follows :—

	No. of cases.
1. Strong wind and well-pronounced tremors	80
2. Strong wind and no tremors, 40 cases which may be subdivided into :	
(a) Cases where tremors ought to have occurred	6
(b) Cases where the wind was local or of short duration, and it is doubtful whether tremors should have been recorded	34
3. With no wind and no tremors	79
4. With no wind and slight tremors, 63 cases, which may be subdivided into :	
(a) Cases where tremors were so small that they were only recorded on one band of paper, 39 + a possible 16 =	55
(b) Cases which may have been due to wind	8
Total	262

The conclusion then is, that out of 86 cases of strong wind there are only six cases where tremors were not observed, while when there was no wind there were no tremors, or, at most, tremors so slight that they were barely recorded. These results agree with the results obtained in previous years.

For three months an automatic spark record was kept of tremors which might be due to vertical motion, but as these only occurred when tremors were recorded by the ordinary tromometer, and were extremely

small, the observations were discontinued. The instrument employed was a horizontal lever spring seismograph with an index having a multiplication of about 100.

In addition to the above-mentioned work large numbers of other investigations have been made. Amongst these may be mentioned a crude attempt to carry out a seismic survey of Tokio, which, so far as it has gone, shows remarkable differences as to the intensity of earthquake movement and the number of earthquakes felt in different parts of the city. The observations which have been made are extremely numerous; and as their analysis will occupy considerable time it is not yet possible to report upon them. Another report which must also be reserved is the work undertaken by a committee summoned by the Government to consider questions relating to construction in earthquake countries. At my suggestion a number of experiments are being made relating to the movement experienced at the time of an earthquake on different kinds of ground, the efficacy of different kinds of foundations, the experimental determination of constants for the stability of masonry and brickwork to suddenly applied horizontal stresses, &c.

Catalogue of Earthquakes recorded at the Meteorological Observatory, Tokio, between June 1887 and June 1888 by the Gray-Milne Seismograph.

Report of the Committee, consisting of Mr. THISELTON-DYER (Secretary), Professor NEWTON, Professor FLOWER, Mr. CARRUTHERS, and Mr. SCLATER, appointed for the purpose of reporting on the present state of our knowledge of the Zoology and Botany of the West India Islands, and taking steps to investigate ascertained deficiencies in the Fauna and Flora.

THE Committee appointed by the Association held its first meeting on January 4, 1888. At this meeting it was decided to co-operate with the Committee appointed for a similar purpose by the Government Grant Committee of the Royal Society. Dr. Günther and Dr. Sharp, the only members of the latter Committee who were not already members of the Association Committee, were therefore added to it, and it was decided to further invite the adhesion of Lieut.-Colonel Feilden, of the Army Pay Department, and of Mr. D. Morris, Assistant-Director of the Royal Gardens, Kew.

Lieut.-Colonel Feilden's official duties will keep him for the next few years in the British West Indies, and for the present he will act as local secretary in Barbados, while Dr. H. A. Alford Nicholls, F.L.S., C.M.Z.S., has kindly agreed to assist in the same capacity in Dominica. In order to commence their investigations without delay the Committee have secured the services of Mr. George A. Ramage, who was lately associated with Mr. Ridley in his expedition to the Island of Fernando Noronha, and has since been collecting at Pernambuco. Mr. Ramage arrived in Dominica in March last, and has proceeded to his work with great zeal. In May, after passing five weeks at Laudat, on the right bank of the Roseau River, about 2,000 feet above the sea-level, he moved to St. Aroment, an estate belonging to Dr. Nicholls just above Roseau, which he found to be a better locality for getting his plants dried. At Laudat he met with great difficulty in this matter on account of the extreme wetness of the climate. Writing in May last, Mr. Ramage speaks of having got, besides his plants, 'a good lot of insects, lizards, small snakes, and land molluscs.' Besides these he had also obtained three examples of *Peripatus*.

Two cases of zoological specimens and one case of botanical specimens have been already received from Mr. Ramage, and one case of living snakes and lizards has been forwarded direct to the gardens of the Zoological Society. A further case of botanical specimens and two cases of animals are now in transit. The collections received are now under examination. They have too recently come to hand to allow of any results being included in the present report.

After spending the summer season in Dominica, Mr. Ramage is proceeding to St. Lucia, whence he will return to Dominica to complete his collections at a later period.

Considerable interest is being shown in the work of the Committee by Government officers and residents in the islands concerned, and hopes are entertained that collections will be made by private enterprise to supplement those made by the collectors engaged by the Committee.

A circular setting forth the objects sought by the Committee has been prepared and printed, and to this have been added hints as regards the special subjects requiring investigation and the best way of preserving specimens for transit to this country.

In order to carry out their instructions to report upon the present state of our knowledge of the zoology and botany of the Lesser Antilles, a bibliography of the existing literature relating to the fauna and flora has been prepared by a Sub-Committee consisting of Mr. Thiselton Dyer and Dr. Sharp. The Committee desire that this should be printed *in extenso* as an appendix to the present report.

The Committee recommend their reappointment with the addition of those gentlemen who have co-operated with them in the work of the past year. They further recommend that a grant of 250*l.* be placed at their disposal.

APPENDIX.

Botanical and Zoological Bibliography of the Lesser Antilles, Caribbean Islands, or Windward and Leeward Islands, West Indies (Tobago to Porto-Rico inclusive).

BOTANY—By W. B. HEMSLEY. ZOOLOGY—By D. SHARP.

This bibliography includes all works and memoirs that the compilers have been able to discover relative to the islands forming the object of the list; but it does not include references to many systematic works of a general character, in which species from the Lesser Antilles are described or mentioned.

Where desirable the same work is named under both Botany and Zoology.

Books relating to more than one island are first enumerated in chronological order, and the islands follow, arranged alphabetically, any special literature being cited under the island to which it refers. The position, size, and elevation of each island are given, and for these particulars we are almost wholly indebted to the Colonial Office List for 1887. Some interesting information has also been obtained from the 'Handbook and Catalogue of the West Indies and British Honduras for the Colonial and Indian Exhibition, 1886.'

BOTANY.

Nominally all the British West Indian Islands are included in Grisebach's 'Flora of the British West Indian Islands,' but that work was mainly based on collections from Jamaica and Trinidad, and the vegetation of the Lesser Antilles is still very imperfectly known. So far as it is known, however, it presents great sameness throughout, and the number of endemic species in each island is either very small or there is none. Moreover it is not anticipated that future investigations will add materially to the number of peculiar forms, and the principal feature of interest in the flora is the direction in which its constituents have extended.

ZOOLOGY.

The list does not include any comprehensive work on the zoology of the Windward Islands, nor of any one of the islands separately. The most complete list appears to be that of the birds by Cory: this group of animals has received more attention than the others, but the work that has been done at it is of a fragmentary nature, and some islands have been little or not at all explored even for birds.

Very little has been published about the mammalia, reptilia, and batrachia. In the case of mammals this might be attributed to there being but few in the archipelago; but in the case of the reptilia and batrachia, at any rate, it is more probably due to want of investigation, as is shown by the fact that Garman's recently (1887) published paper consists, to a considerable extent, of descriptions of novelties.

The land Mollusca are known chiefly by lists published by naturalists a generation or more ago of the species of the islands of the group belonging to France; but less has been done in the other islands, and investigation even in this comparatively rich and favourite class has apparently been very unequal.

A most singular dearth of information exists as regards the Arthropoda, and in this—the most extensive department of zoology—nearly everything remains to be done. Undoubtedly a considerable number of insects and other arthropods from the Lesser Antilles exist in collections, but they are rare and indicate that very little has been done in collecting; while insular lists are almost entirely wanting, and there is no information as to the distribution of the species in the various islands.

The bibliography includes a considerable number of memoirs on marine zoology, but it is not necessary to remark on these, as it is presumed that the exploration of marine zoology will be considered by the Committee as subordinate in present importance to that of the terrestrial fauna.

The abbreviations of titles of several works are those used in the 'Zoological Record.'

Books and Papers referring to the West Indies generally or to more than one island, chronologically arranged.

ZOOLOGY.

Tertre, J. B. du. Histoire générale des îles de S. Christophe, de la Guadeloupe, de la Martinique et autres dans l'Amérique . . . de plus la description de tous les animaux de la Mer, de l'Air et de la Terre . . . &c. Paris, 1654, pp. 481.

The 'quatrième partie,' divided into three chapters, is devoted to zoology.

Rocheftort, C. de. Histoire Naturelle et Morale des îles Antilles de l'Amérique, enrichie d'un grand nombre de belles Figures en taille douce, qui représentent au naturel les Places et les Raretez les plus considérables qui y sont décrites. Rotterdam, 1681. Dernière édition.

Gives much information as to the zoology of different islands of the Lesser Antilles. The first edition, published 1658, I have not seen.

Sloane, H. A voyage to the islands Madeira, Barbados, Nieves, St. Christopher's, and Jamaica, with the Natural history of the Herbs and Trees, Four-footed Beasts, Fishes, Birds, Insects, &c., of the last of those islands. 2 vols. London, 1707.

The information in this work about the zoology of the Lesser Antilles is almost *nil*.

Labat, P. Nouveau Voyage aux Iles d'Amérique, contenant l'histoire naturelle de ces pays, l'Origine, les Mœurs, la Religion et le Gouvernement des Habitants anciens et modernes, &c., &c. Paris, 1722. 10 vols.

Contains chapters on the zoology of the French islands. An edition in two vols. 4to was published at La Haye in 1724. (See also BOTANY.)

West, H. Bidrag til beskrivelse over Ste Croix med en kort udsigt over St. Thomas, St. Jan, Tortola, Spanishtown og Crabeneiland. Copenhagen, 1793.

Includes a chapter on the reptiles, fishes, and crustaceans.

Ledru, A. P. Voyage aux îles de Ténériffe, La Trinité, Saint-Thomas, Sainte-Croix et Porto-Ricco. . . . Paris, 1810. 2 vols.

Contains chapters on the natural history of the Danish islands and Porto Rico, including lists of the animals found there.

Leblond, J. B. Voyage aux Antilles et à l'Amérique méridionale, commencé en 1767 et fini en 1802. Paris, 1813, pp. 474.

Slight and unimportant observations on zoology.

Waterton, C. Wanderings in South America, the North-west of the United States, and the Antilles. London, 1825.

Information about the Antilles is brief and unimportant.

Ferguson, W. On the Poisonous Fishes of the Caribbee Islands. 'Tr. R. Soc. Edinb.' ix. (1823), pp. 65-79.

Devoted to the economical, not the zoological, aspect of the subject.

Guilding, L. Observations on the Zoology of the Caribbean Islands. 'Zool. Journ.' iii. (1828), pp. 403-408 and 527-544; *op. cit.* iv. (1829), pp. 164-175.

Contents—'Radiata Caribbæana,' 'Mollusca Caribbæana,' 'Notice of the living Guana of the West Indies,' 'Analecta zoologica,' 'Notice of the discovery of a recent Encrinus.'

Guilding, L. An account of Margarodes, a new genus of insects found in the neighbourhood of Ants' Nests. 'Tr. Linn. Soc.' xvi. (1883), pp. 115-119. Plate XII.

Occurs in Antigua. Other papers by this author exist in the 'Tr. L. Soc.' xiv.-xvi., in which insects from the West Indies are described. St. Vincent is in these cases the probable locality.

Hartlaub, G. Ueber den heutigen Zustand unserer Kenntnisse von Westindiens Ornithologie. 'Isis,' 1847, pp. 603-615.

Recapitulates what was known as to the ornithology of the islands (including Porto Rico, St. Thomas, Guadeloupe, Martinique, Barbados, and Tobago) in 1847.

Duchassaing, P. Animaux radiaires des Antilles. Paris, 1850. Pp. 35. Plate II.

Special localities are scarcely mentioned.

Duchassaing, P. Note sur les mœurs des Crustacés des Antilles. 'Rev. et Mag. Zool.' (2) iii. (1851), pp. 77-81.

11 species: probably relates to Guadeloupe, though it does not say so.

Pfeiffer, L. Beiträge zur Molluskenfauna Westindiens. 'Mal. Blatt.' ii. 1856, pp. 98-106.

Several new species from St. Croix and St. Thomas.

Shuttleworth, R. I. Description de nouvelles espèces. Première décade; espèces nouvelles pour la faune des Antilles. 'J. de Conch.' v. (1856), pp. 168-175.

Shells from Guadeloupe, St. Thomas, Porto Rico.

Beau, —. De l'utilité de certains Mollusques marins vivant sur les côtes de la Guadeloupe et de la Martinique. 'J. de Conch.' iii. (1858), pp. 25-40.

Bland, T. Notes on certain terrestrial Molluscs which inhabit the West Indies. 'Ann. Lyc. New York,' vi. (1858), pp. 147-155.

Relates to several of the islands of the Lesser Antilles.

Saussure, H. de. Mémoire sur divers Crustacés nouveaux des Antilles et du Mexique. 'Mém. Soc. Phys. Genève,' xiv. (1858), pp. 417-496. Plates i.-vi.

Several species from Guadeloupe and St. Thomas, besides others from the larger islands.

Saussure, H. de. Mémoires pour servir à l'histoire naturelle du Mexique, des Antilles et des Etats-Unis. Tome premier: 1^{re} livraison: Crustacés. Geneva, 1858. 2^{me}: Myriapodes. 1860. 3^{me} et 4^{me}: Orthoptères-Blattides. Geneva, 1864-5. Tome 2^{me}: Mantides Américains. Geneva, 1871.

These relate only in small part to the Lesser Antilles.

Sclater, P. L. Descriptions of two new species of American Parrots. 'Ann. N. H.' (3), 4 (1859), pp. 224-226.

Includes list of the parrots of the Antilles, including Porto Rico, St. Thomas, and St. Vincent.

Duchassaing, P., and Michelotti, J. Mémoire sur les Corallaires des Antilles. 'Mém. Acc. Tor.' (2), xix. (1861), pp. 279-365. Plates I.-X. with supplement in vol. xxiii. 1866, pp. 97-206. Plates I.-XI.

Important memoirs, enumerating 400 species from St. Thomas, Guadeloupe, St. Croix, Tobago, Barbados, and in fact most of the islands.

Bland, T. On the geographical distribution of the Genera and Species of Land Shells of the West India Islands, with a catalogue of the Species of each island. 'Ann. Lyc. New York,' vii. (1862), pp. 335-361.

The Lesser Antilles are treated as one island.

Reinhardt, J., and Lütken, C. F. Bidrag til det vestindiske Origes og navnligen til de dansk-vestindiske Öers Herpetologie. 'Vid. Medd.' 1862, pp. 153-291.

In this list of the West Indian reptiles the Lesser Antilles are treated as one group (Karabaiske Öer).

Stimpson, W. Notes on North American Crustacea, Nos. I. and II. 'Ann. Lyc. New York,' vii. (1862), pp. 49-93, pl. i., and pp. 176-246. Plates II., III.

Includes several new species from St. Thomas and Bardados.

Mörch, O. A. L. Contributions à la Faune malacologique des Antilles danoises. 'J. de Conch.' xi. (1863), pp. 21-43.

Numerous species, including several new, from St. Thomas, St. Croix, St. Vincent.

Duchassaing, P. de F., and Michelotti, G. Spongiaires de la Mer Caraïbe. 'Nat. Verh. Wet. Haarlem,' xxi. (1864), p. 115. Plate XXV.

A large number of new species are described from various islands of the Lesser Antilles, most of them from St. Thomas.

Lütken, Chr. Om Vestindiens Pentacriner. 'Vid. Medd.' 1864, pp. 195-245. Plates IV. and V.

Pentacrinus Mülleri. 'Danish Islands.'

Bland, T. Remarks on the Origin and Distribution of the operculated land-shells which inhabit the continent of America and the West Indies, with a catalogue of the American species. 'Am. J. Conch.' ii. (1866), pp. 54-63, 136-143.

'Origin' means the 'maximum specific representation.'

Bland, T. Remarks on the distribution of the inoperculated land-shells which inhabit the continent of America and the West Indies. T. c. pp. 349–370.

Guyon, —. Des animaux disparus de la Martinique et de la Guadeloupe depuis notre établissement dans ces îles. 'Comptes Rendus,' lxxiii. (1866), pp. 589–593.

8 species. 1 mammal, 6 birds, 1 frog.

Crosse, H., and Fischer, P. Note sur la distribution géographique des Brachiopodes aux Antilles et description d'espèces nouvelles de la Guadeloupe. 'J. de Conch.' xiv. (1866), pp. 265–273.

5 species catalogued, 2 described, from Martinique and Guadeloupe.

Bland, T. Notes on the Land-shells of Trinidad, Grenada, and Dominica, and also of Curaçao and Buen Ayre, W. I.. 'Am. Journ. Conch.' iv. (1868), pp. 177–192.

14 species from Grenada, 21 from Dominica.

Guppy, R. J. L. On the terrestrial Mollusks of Dominica and Grenada, with an account of some new species from Trinidad. 'Ann. Mag. Nat. Hist.' (4) i. (1868), pp. 429–442.

20 species, 3 new.

Bland, T. Additional notes on the geographical distribution of Land-shells in the West Indies. 'Ann. Lyc. N. York,' ix. (1870), pp. 238–241.

Lists of species from Anegada, Anguilla, and St. Bartholomew.

Duchassaing, P. de F. Revue des Zoophytes et des Spongiaires des Antilles. Paris, 1870.

Bland, T. Notes relating to the physical geography and geology of, and the distribution of Terrestrial Mollusca in, certain of the West India Islands. 'P. Am. Phil. Soc.' xii. (1871), pp. 56–63.

Cope, E. D. Contribution to the Ichthyology of the Lesser Antilles. 'Tr. Am. Phil. Soc.' xiv. (1871), pp. 445–483.

Records a large number of species, including several new. Most of the islands are mentioned.

Dall, W. H. Report on the Brachiopoda obtained by the United States Coast Survey Expedition, in charge of L. F. de Pourtales. 'Bull. Mus. C. Z.' iii. No. 1 (1871), pp. 1–42.

Chiefly a systematic paper, but mentions a few species from Guadeloupe, &c.

Elliott, D. G. The Humming-birds of the West Indies. 'Ibis,' 1872, pp. 345–357.

The species are enumerated, and the islands in which each has been found mentioned.

Saussure, H. D., and Humbert, A. Catalogue général des Myriapodes américains in 'Miss. Sci. au Mexique et l'Amér. centr. Zool.' (1872) 6^{me} partie, 2^e section, pp. 149–211.

Includes the species known to occur in the Antilles. St. Thomas, Martinique, Porto Rico, St. Vincent, St. Croix, St. Bartholomew are mentioned as localities of a few species.

Stimpson, W. Notes on North American Crustacea in the Museum of the Smithsonian Institute. 'Ann. Lyc. New York,' x. (1874), pp. 92–136.

Includes several new species from Barbados and St. Thomas.

Lyman, T. Zoological results of the 'Hassler' Expedition. 'Cat. Mus. C. Z.' viii. 2 (1875). Ophiuridæ and Astrophytidæ, pp. 1–34. Plates. I.–V. Numerous species, some new, from Barbados.

Lindström, G. Contributions to the Actinology of the Atlantic Ocean. 'K. Svensk. Vet. Ak. Hand.' xiv. 2 (1876), No. 6, 26 pp. 3 plates.

Many species of corals from St. Bartholomew, and a few from other islands of the Lesser Antilles are recorded in this list.

Wallace, A. R. The geographical distribution of animals. 'The West Indian Islands, or Antillean Sub-region,' vol. ii. (1876), pp. 60-80.

Edwards, H. Milne. Recherches zoologiques pour servir à l'histoire de la Faune de l'Amérique centrale et du Mexique. 'Miss. Sci. au Mexique et l'Amérique centr. Zool.' 5^{me} partie, Xiphosures et Crustacés. Paris, 1873-1880.

Includes species from various islands of the Lesser Antilles.

Martens, E. V. Land- und Süßwasser-Schnecken von Puertorico. 'J. B. mal. Ges.' iv. 1877, pp. 340-362.

120 species from Porto Rico are mentioned, and there is a table of the distribution of the species in the West Indies, including the Lesser Antilles.

Lawrence, G. N. A general catalogue of the birds noted from the islands of the Lesser Antilles visited by Mr. Fred A. Ober, with a table showing their distribution, and those found in the United States. 'P. U. S. Nat. Mus.' i. (1878), pp. 486-488.

A list of 128 species from all the islands.

Lawrence, G. N. Catalogue of the birds of Antigua and Barbuda, from collections made for the Smithsonian Institut by Mr. Fred A. Ober, with his observations. 'P. U. S. Nat. Mus.' i. (1878), pp. 232-242.

39 species, including a new *Speotyto*.

Poulsen, C. M. Catalogue of West Indian Shells in the collection of C. M. Poulsen. Copenhagen, 16 pp. 1878.

The Land-shells of the Lesser Antilles are given in two separate lists.

Marshall, T. A. Notes on the entomology of the Windward Islands. 'P. Ent. Soc. Lond.' 1878, pp. xxvii-xxxviii.

A few species of various orders from Antigua and Martinique.

Waterhouse, C. O. Notice of a small collection of Coleoptera from Jamaica, with descriptions of new species from the West Indies. 'Tr. Ent. Soc. Lond.' 1878, pp. 303-311.

Includes two or three species from St. Thomas and St. Bartholomew.

Gibbons, J. S. Notes on the Habits and Distribution of certain West Indian *Pulmonifera*. 'J. Conch.' ii. (1879), pp. 129-134.

Mentions a few species from various islands of the Lesser Antilles.

Lawrence, G. N. Descriptions of supposed new species of birds from the islands of Grenada and Dominica, West Indies. 'Ann. N. York Ac.' i. (1879), pp. 160-163.

4 species.

Schmidt, O. Die Spongien des Meerbusen von Mexico (und des Caraibischen Meeres. Heft I. Jena, 1879, 4 pls. Zweites (Schluss-) Heft, pp. 33. Plates V.-X. Jena, 1880.

The new species described in the first Heft are mostly from Havannah, but there are a few from Sombrero and Barbados; those in the second Heft are mostly from the Lesser Antilles.

Théel, H. Reports on the results of dredging under the supervision of Alexander Agassiz in the Gulf of Mexico (1877-78), in the Caribbean

Sea (1879–80) . . . &c., &c. Report on the *Holothurioidea*, 'Bull. Mus. C. Z.' xiii. No. 1, pp. 1–21, pl. i.

New species from off several islands of the Lesser Antilles.

Cope, E. D. Eleventh contribution to the Herpetology of Tropical America, vi., vii. 'P. Am. Phil. Soc.' xviii. (1880), pp. 274–277.

These parts relate to Dominica (with four species, three of them new) and Tobago (one new sub-species).

Kobelt, W. Die geographische Verbreitung der Mollusken. III. Die Inselfaunen. 'J. B. mal. Ges.' vii. 1880, pp. 243–286.

Gives lists of the species known from each island.

Lawrence, G. N. Description of a new species of *Icterus* from the West Indies. 'P. U. S. Nat. Mus.' iii. (1880), p. 351.

From Montserrat.

Ober, F. A. Camps in the Caribbees; the adventures of a naturalist in the Lesser Antilles. Edinburgh, 1880, pp. xviii and 366.

The author, the discoverer of the species of birds described by Lawrence in his memoirs, gives a few field-notes relating to birds.

Pourtales, L. F. Reports on the results of dredging, under the supervision of Alexander Agassiz, in the Caribbean Sea, 1878–79, by the United States Coast Survey steamer 'Blake.' VI. Report on the *Corals* and *Antipatharia*. 'Bull. Mus. C. Z.' vi. No. 4 (1880), pp. 95–120. Plates I.–III.

Numerous species, some new, are mentioned; the stations are nearly all off the islands of the Lesser Antilles.

Agassiz, A. Reports on the results of dredging by the United States Coast Survey steamer 'Blake.' IX. Preliminary Report on the Echini. 'Bull. Mus. C. Z.' viii. (1880–81) pp. 69–84.

The localities for each species are nearly all in the Lesser Antilles.

Thomson, Sir C. W., and Murray, J. The Voyage of H.M.S. 'Challenger.' 'Zoology,' vols. i.–xxv. London, 1880–88.

These volumes contain additions to the marine fauna of the West India Islands.

Edwards, A. Milne. Reports on the results of dredging, under the supervision of Alexander Agassiz, in the Gulf of Mexico and in the Caribbean Sea, by the U. S. Coast Survey steamer 'Blake.' VIII. Études préliminaires sur les Crustacés. 'Bull. Mus. C. Z.' viii. (1880–81) pp. 1–69. Plates I., II.

The localities given are chiefly the various islands of the Lesser Antilles: 214 species are mentioned, and many new are described.

Fewkes, J. W. Reports on the results of dredging by the United States Coast Survey steamer 'Blake.' XI. Report on the Acalephæ. 'Bull. Mus. C. Z.' viii. (1880–81), pp. 127–140. Plates I.–IV.

Several new species are described and the localities given are mostly islands of the Lesser Antilles.

Garman, S. Reports on the results of dredging by the United States Coast Survey steamer 'Blake.' XII. Report on the Selachians. 'Bull. Mus. C. Z.' (1880–81) pp. 231–237.

Some of the Lesser Antilles are mentioned as localities for two species.

Lethierry, L. Liste des Hémiptères recueillis par M. Delaunay à la Guadeloupe, la Martinique et Saint Barthélemy. 'Ann. Ent. Belg.' xxv. C. (1881), pp. 8–19.

62 species, several new, mostly from Guadeloupe.

Carpenter, P. H. Report on the results of dredging by the United States Coast Survey steamer 'Blake.' XVI. Preliminary Report on the Comatulæ. 'Bull. Mus. C. Z.' ix. (1881-82), pp. 151-170. Plate I.

New species of Antedon from Guadeloupe and Martinique.

Carter, H. J. Some Sponges from the West Indies and Acapulco in the Liverpool Free Museum described, with general and classificatory remarks. 'Ann. N. H.' (5), ix. (1882), pp. 266-301, and 346-368. Plates XI., XII.

Includes several new species from different islands of the Lesser Antilles.

Stejneger, L. Synopsis of the West Indian *Myadestes*. 'P. U. S. Nat. Mus.' v. (1882), pp. 15-27. Plate II.

Two new species from Saint Lucia and Dominica.

Traustedt, P. A. Vestindiske Ascidie simplices. 'Vid. Medd.' 1881, pp. 257-288, plates IV., V., and 1882, pp. 108-136, plates V., VI.

Several new species are described from St. Thomas, St. Croix, and other islands.

Mazé, H. Catalogue révisé des Molusques terrestres et fluviatiles de la Guadeloupe et de ses dépendances. 'J. de Conch.' xxxi. (1883), pp. 5-54.

80 species from Guadeloupe, 25 from Saintes, 16 from Marie-Galante, 9 from La Désirade.

Lyman, T. Reports on the results of dredging by the United States Coast Survey steamer 'Blake.' XX. Report on the Ophiuroidea. 'Bull. Mus. C. Z.' x. (1882-83), pp. 227-287. Plates I.-VIII.

The localities of the numerous species are chiefly islands of the Lesser Antilles.

Carpenter, P. H. Report on the results of dredging by the United States Coast Survey steamer 'Blake.' XVIII. The stalked Crinoids of the Caribbean Sea. 'Bull. Mus. C. Z.' x. (1882-83), pp. 165-181.

Includes an additional species and Caribbean localities for the other species mentioned.

Agassiz, A. Reports on the results of dredging . . . xxiv. Part I. Report on the Echini. 'Mem. Mus. C. Z.' x. No. 1 (1883), pp. 1-94. Plate XXXII.

Includes list of the Echini of the West Indies.

Graff, L. v. Reports on the results of dredging, under the supervision of Alexander Agassiz . . . xxvi. Verzeichniss der von den United States Coast Survey steamers 'Hassler' und 'Blake' von 1867 zu 1879 gesammelten Myzostomiden. 'Bull. Mus. C. Z.' xi. (1883), pp. 125-133.

Reitter, E. Beitrag zur Kenntniss der *Clavigeriden*, *Pselaphiden* und *Scydmaeniden* von West Indien (*Coleoptera*). 'Deutsche ent. Zeit.' xxvii. (1883), pp. 33-46.

21 species, mostly from St. Thomas, nearly all new. Found by Baron V. Eggers.

Verrill, A. E. Report on the results of dredging under the supervision of Alexander Agassiz on the east coast of the United States . . . by the U. S. Coast Survey steamer 'Blake.' XXI. Report on the Anthozoa. 'Bull. Mus. C. Z.' xi. No. 1 (1883), pp. 1-72. Plates I.-VIII.

Goode, G. B., and Bean, T. H. Reports on the results of dredging by the United States Coast Survey steamer 'Blake.' XXVIII. Description of thirteen species and two genera of fishes from the 'Blake' Collection. 'Bull. Mus. C. Z.' xii. (1885-86), pp. 153-170.

The localities given are chiefly islands of the Lesser Antilles.

Ridgway, R. Description of three supposed new Honey-creepers from the Lesser Antilles, with a synopsis of the species of the genus *Certhiola*. 'P. U. S. Nat. Mus.' viii. (1885), pp. 25-30.

2 new species from Guadeloupe and Dominica.

Dall, W. H. Reports on the results of dredging, under the supervision of Alexander Agassiz in the Gulf of Mexico (1877-78) and in the Caribbean Sea (1879-80) by the U. S. Coast Survey steamer 'Blake.' Report on the Mollusca. Part I., *Brachiopoda* and *Pelecypoda*. 'Bull. Mus. C. Z.' xii. No. 6 (1886), pp. 171-318. Plates I.-IX.

Many species from the Lesser Antilles, including Barbados.

Cory, C. B. Descriptions of new species of birds from the West Indies. 'Auk,' iii. (1886), pp. 381, 382.

Guadeloupe, St. Lucia, Barbados.

Cory, C. B. On a collection of birds from several little-known islands of the West Indies. 'Ibis,' 1886, pp. 471-475.

Lists of species found in Barbados, St. Vincent, Marie-Galante, La Désirade, Grande Terre, St. Lucia.

Cory, C. B. The Birds of the West Indies, including the Bahama Islands, the Greater and Lesser Antilles, excepting the islands of Tobago and Trinidad. 'Auk,' iii. (1886), pp. 1-59, 187-245, 337-381, and 454-472; *op. cit.* iv. (1887), pp. 37-51, 108-120, 223-232, 311-328; *op. cit.* v. (1888), 48-82 and 155-159.

A complete list with references, synonymy, brief characters, and woodcuts of heads.

Jordan, D. S. A Preliminary List of the fishes of the West Indies. 'P. U. S. Nat. Mus.' ix. (1886), pp. 554-608.

Nearly 900 species.

Garman, S. On West Indian Reptiles in the Museum of Comparative Zoology at Cambridge, Mass. 'P. Am. Phil. Soc.' xxiv. (1887), pp. 278-286.

Refers to snakes, turtles, and crocodiles, and records several species from the Lesser Antilles.

Garman, S. On West Indian Reptiles in the Museum of Comparative Zoology, Cambridge, Mass. 'Bull. Essex Institute' xix. (1887), pp. 1-53.

Several new species from various islands of the Lesser Antilles, as well as the larger islands and Trinidad.

Agassiz, A. Three cruises of the United States Coast and Geodetic Survey steamer 'Blake' in the Gulf of Mexico, in the Caribbean Sea, and along the Atlantic coast of the United States from 1877 to 1880. Vols. i. and ii. London, 1888.

Chap. V. vol. i. 'Relations of the West Indian Fauna and Flora,' and Chap. XIV. vol. ii. 'The West Indian Fauna,' relate to the fauna of the Lesser Antilles and Caribbean Sea. The larger portion of the memoirs on marine zoology recorded in this bibliographical list are the results of these cruises, and it may therefore be well to state that the fauna referred to in them is that extending from the hundred-fathom line to deep water off the lee side of the Caribbean islands. Cf. vol. i. Introduction, p. xii.

ANEGADA (SEE VIRGIN ISLANDS).

ANGUILLA.

About sixty miles north-west of St. Kitts, in 18° 12' N. lat. The area is thirty-five square miles and the elevation very slight. The adjacent Dog and Sombrero Islands belong to Anguilla politically.

Owing to great droughts and the absence of fresh-water springs, this island is not very fertile, yet a considerable amount of garden produce is raised and finds a ready market in St. Thomas.

Seal and Scrub are islets a little north of Anguilla, and regarded as appendages to it.

ANTIGUA.

Situated in $17^{\circ} 5' N.$ lat. and $61^{\circ} 50' W.$ long., and about seventy miles in circumference. The mountains reach a height of 2,200 feet, but the vegetation is not so luxuriant as in most of the neighbouring islands on account of the comparatively small rainfall.

Five Islands are on the western side.

BOTANY.

Very complete collections of plants were made in this island by Wulfschlägel and elaborated by Grisebach in his 'Flora of the British West Indies.' Only one endemic flowering plant, a grass (*Bouteloua elatior*) is recorded, and that, as Grisebach remarks, may occur elsewhere.

The vegetation of this and the other non-volcanic islands seems to be of comparatively recent derivation, like that of the Bahamas and the more distant Bermudas.

'Report upon Antigua in Relation to Forestry.' By E. D. M. Hooper. Indian Forest Department, Colonial Office, 1888.

ZOOLOGY.

Putzeys, J. Note sur les Cicindèles et Carabiques recueillis dans l'île d'Antigua par M. Purves. 'Ann. Ent. Soc. Belg.' xvii. pp. 117-120. 10 species, 2 new.

Purves, —. Shells of Antigua. 'Bull. Malac. Belg.' vii. (1872), pp. xcix-ci.

He found 38 species, only 6 being previously known from the island.

Roelofs, W. Note sur les Curculionides recueillis par M. Purves à l'île d'Antigua. 'C. R. Ent. Soc. Belg.' xviii. pp. 25, 26.

The species previously described (3) are mentioned, 6 are undescribed, one of them here described.

Sharp, D. Aquatic Coleoptera collected by M. J. C. Purves in Antigua during the summer of 1872. 'Ann. Ent. Belg.' xx. pp. 120, 121.

13 species, one new.

Lameere, A. Longicornes recueillis par M. Purves à Antigua. 'Ann. Ent. Belg.' xxviii. pp. 100, 101.

5 species.

BARBADOS.

Situated in $13^{\circ} 4' N.$ lat. and $59^{\circ} 30' W.$ long., and the most easterly of the West Indian islands. It is nearly twenty-one miles long by fourteen in breadth, and has an area of 166 square miles. The eastern side is very rugged and the greatest elevation 1,150 feet above the level of the sea.

BOTANY.

Ligon, R. A History of the Island of Barbados. London, 1657, and reprinted in 1673 . . . Principal trees and plants, pp. 66-84, with curious illustrations.

1888.

Hughes, Griffith. The Natural History of the Barbados. In 10 books. London, 1750. Folio, pp. 314, tt. 29. Botany, pp. 97–256.

Maycock, J. D. Flora Barbadosensis. London, 1830. 8vo, with a geological map.

Schomburgk, R. The History of Barbados. London. 1848. 8vo. 'Botany,' pp. 573–633.

Notwithstanding that the vegetation of Barbados has been dealt with by so many different writers, it has not been critically and exhaustively elaborated. It possesses, however, no special interest. Schomburgk enumerates 896 species of flowering plants; yet, according to Grisebach ('Geograph. Verbr. Pflanz. W. Ind.'), only one species is peculiar to the island against twelve in St. Vincent and twenty-nine in Dominica. 'Hughes' Natural History' is a fine old work, containing admirable engravings by Ehret.

ZOOLOGY.

Ligon, R. A true and exact History of the island of Barbados. London, 1657. 122 pp. Woodcuts.

Pp. 60–65 relate to the birds, lesser animals, and insects.

Hughes, G. The Natural History of Barbados. In 10 books. London, 1750.

Includes particulars about the 'quadrupeds, volatiles, and insects.'

BARBUDA.

A small and very flat island, about half a degree north of Antigua in 17° 40' N. lat. The population is small, and chiefly engaged in breeding cattle and horses. Vegetation consists mainly of brushwood.

LA DESIRADE (SEE GUADELOUPE).

DOMINICA.

This island lies between the French islands of Guadeloupe to the north-west, and Martinique, to the south-east, in 15° 20' N. lat. and

61° W. long. It is twenty-nine miles long by sixteen broad, with an area of 292 square miles, and the mountains attain an altitude of nearly 5,000 feet.

BOTANY.

Johow, F. Vegetationsbilder aus Westindien: eine Excursion nach dem Kochenden See auf Dominica. 'Kosmos,' ii. 1884, pp. 112-130, 270-285. Abstract in 'Engler's Jahrbücher,' vii. (1886), 'Literaturbericht,' p. 76.

Nicholls, H. A. A. The Natural Resources of Dominica. Handbook of the West Indies and British Honduras, Colonial and Indian Exhibition, 1886. Vegetation, &c., pp. 120-126.

Dominica shares with Guadeloupe a comparatively rich flora, and has been almost thoroughly botanised by Dr. Imray, whose collections were elaborated by Grisebach in his Flora of the British West Indies, and subsequently by Baron Eggers, who, from time to time, has sent to Kew specimens of about 250 species of flowering plants. The forests are described as extensive, and abounding in valuable timber. Indeed it is stated that only 55,000 acres, out of 186,000, are under cultivation, and that the rest of the land is for the most part covered with virgin forests. So far as Grisebach's data go, Dominica is by far the richest in endemic species of all the Lesser Antilles; yet it is barely half the size of Guadeloupe, immediately to the north, and the nearer Martinique to the south. Twenty-nine species of flowering plants are apparently endemic in Dominica, against two in Martinique and one in Guadeloupe.

GRANDE TERRE (SEE GUADELOUPE).

GRENADA.

Situated between 11° 58' and 12° 30' N. lat. and 61° 20' to 61° 35' W. long., and about 68 miles south-west of St. Vincent. About 21 miles long by 12 miles in its greatest breadth, with an area of 125 square miles. Mountainous and picturesque and abounding in streams. The Grand Etang, a lake on the summit of the mountain ridge, at an elevation of 1,740 feet, is one of the most remarkable natural features. About 17,000 acres, out of a total of 76,653, are cultivated, but much of the uncultivated land is described as inaccessible. Valuable timber is reported to be abundant, particularly bullet-tree (? *Sideroxylon*), locust (*Hymenæa*), mahogany (*Swietenia*), white cedar (*Cedrela*), and galba (*Calophyllum*). Vanilla and several varieties of gum-yielding trees have lately been discovered.

BOTANY.

This island has never been thoroughly botanised, but it is one of those visited by Jacquin about the middle of the last century, and Mr. G. Murray, of the British Museum, spent two or three weeks there in 1887. Recently a small botanic garden has been established, and Mr. Elliott, the present superintendent, has already partially explored the island botanically, and sent a small collection of dried plants to Kew, from which it appears that there are very few, if any, plants peculiar to the island.

GRENADINES.

A group of small islands lying between Grenada and St. Vincent, many of them being little more than rocks. Bequia and Carriacou are the largest. Other named islands are Ronde, The Sisters, Les Tantes, Savan, Hillsborough, Frigate, Union, Little Martinique, Bird, Mayero, Cannonan, Little Cannonan, Sail, Quatre, Moustique, and Baliceaux.

Mr. D. Morris informs us that these islands have been practically denuded of their timber trees to supply Barbados with fuel.

GADELOUPE.

Including the adjacent islands of Marie-Galante, Petite Terre, Les Saintes, and La Désirade. This group extends from 15° 55' to 16° 30' N. lat. and from 60° 57' to 61° 50' W. long. The main island consists of two nearly equal areas, Grande Terre and Guadeloupe proper, connected by a very narrow neck of land. Total area estimated at 635 square miles, and the greatest altitude exceeds 5,000 feet.

Grisebach ('Verbreitung der Pflanzen Westindiens') indicates only one very distinct flowering plant as endemic in Guadeloupe, namely, *Cremanium coriaceum* (Melastomaceæ). Yet this island is one of the most thoroughly explored botanically.

MARIE-GALANTE (SEE GUADELOUPE).

MARTINIQUE.

Situated between 14° 23' and 14° 52' N; lat. and 60° 45' and 62° 15' W. long., and about fifty miles long by sixteen in the broadest part, with an area of about 380 square miles. The mountains reach an elevation of nearly 4,500 feet.

BOTANY.

Chanvalon, Thibault de. Voyage à la Martinique. Paris, 1763. 4to.
See general bibliography for works dealing with the botany of this and other French islands.

The botany of Martinique has been so far investigated that large collections of the plants have been dried and distributed to the principal herbaria, but no complete enumeration of them has been published. Hahn was perhaps the largest collector, and the set of his plants in the Kew Herbarium contains about 675 species of flowering plants and forty ferns. Apparently the endemic element is very poor, for only two species of flowering plants were regarded by Grisebach as peculiar to this island.

14 species.

NEVIS.

This island lies to the south-east of St. Kitts, from which it is about two miles distant. Its area is about 50 square miles, and its greatest elevation 3,200 feet.—Redonda is a very small island between Nevis and Montserrat.

BOTANY.

Smith, Rev. W. A Natural History of Nevis and the rest of the English Leeward Caribbee Islands. Cambridge, 1745.

Sloane visited Nevis, but made no collections there.

ZOOLOGY.

For some fragmentary observations on zoology see Smith's work in botany above.

PETITE TERRE (SEE GUADELOUPE).

PORTO RICO.

This is by far the largest of the islands in the chain eastward of San Domingo. It is situated between 18° to $18^{\circ} 30' N.$ lat. and $65^{\circ} 35'$ and $67^{\circ} 20' W.$ long., and has an area of nearly 3,700 square miles, the mountains rising to a height of 3,000 feet.—Mona is a small island lying between Porto Rico and San Domingo.

BOTANY.

At present no complete account of the botany exists, but large collections of dried plants have been made, the latest by Mr. Sintenis being perhaps the most important. Baron Eggers and Mr. Garber have also added to our knowledge of the flora of the island.

Dr. J. Urban, of Berlin, is preparing, with the co-operation of other botanists, a complete 'Flora of Porto Rico, San Domingo, and Cuba.'

Bello y Espinosa, Don Domingo. Apuntes para la Flora de Puerto Rico. 'Anal. Soc. Esp. Hist. Nat.' x. 1881, pp. 231-304, xii. 1883, pp. 103-130, tt. 3.

35 species, a few new, of butterflies and moths.

ST. CHRISTOPHER (SEE ST. KITTS).

ST. CROIX, OR SANTA CRUZ.

In 17° 45' N. lat. and 64° 50' W. long., and about twenty miles from east to west and five miles in its greatest breadth, with an area of fifty-seven square miles. The hills average from 600 to 800 feet high, and the highest point, Mount Eagle, reaches 1,150 feet.

BOTANY.

Eggers, H. F. A. St. Croix's Flora. 'Videnskabelige Meddelelser fra den naturhistoriske Forening i Kjöbenhavn,' 1876, pp. 33, with a phytogeographical map.

Eggers, H. F. A. The Flora of St. Croix and the Virgin Islands. Bulletin of the United States National Museum, No. 13. Washington, 1879. 8vo. pp. 133.

Baron Eggers has fully investigated the flora of St. Croix, and he tabulates it in the work cited above. There are no endemic flowering plants, and the total number of vascular plants regarded as indigenous is 666. These include only three orchids, namely, *Epidendrum bifidum*, *E. ciliare*, and *E. cochleatum*. *Oreodoxa regia* is common, and of the only other native palm, *Thrinax argentea*, only one specimen was seen.

ST. EUSTATIUS, OR ST. EUSTACHE.

A small island lying between St. Kitts and Saba, in about 63° W. long. and 17° 30' N. lat. It rises in a pyramidal form from the sea to a height of nearly 2,000 feet.

ST. KITTS, OR ST. CHRISTOPHER'S.

Situated to the north-west of Antigua, in 17° 20' N. lat. and 62° 45' W. long., and having an area of sixty-eight square miles. Mount Misery, the highest peak, has an altitude of 4,060 feet.

BOTANY.

'The higher slopes of the mountains are clothed with grass, while their summits are crowned with noyau or ironwood, Spanish ash, red sweetwood, wild mahoe, snakewood, white box, dogwood, and other forest trees.'—Handbook of the West Indies and British Honduras, Colonial and Indian Exhibition, 1886.

ZOOLOGY.

Lawrence, G. N. Description of a new sub-species of *Loxigilla* from the island of St. Christopher, West Indies. 'P. U. S. Nat. Mus.' iv. (1881), p. 204.

ST. LUCIA.

One of the most picturesque of the Windward Islands, situated south of Martinique, in 14° N. lat. and 61° W. long. It is forty-two miles long and twenty-one in its greatest breadth, with an area of 243 square miles. The greatest altitude is about 3,300 feet, and here, as in St. Vincent, there is a 'souffrière,' or sulphur mountain.

Maria, Gros, and Pigeon are adjacent islets.

BOTANY.

There is no complete account of the botany of this island. Grisebach saw very few plants thence, including a solitary endemic species.

ST. MARTIN.

'To the south of Anguilla, in $18^{\circ} 4'$ N. lat. and $63^{\circ} 5'$ W. long., and having an area of thirty square miles and an elevation of nearly 2,000 feet.—Tintamarre is an islet on the north-east side of St. Martin.

ST. THOMAS (SEE VIRGIN ISLANDS).

ST. VINCENT.

This island is in $13^{\circ} 10'$ N. lat. and $60^{\circ} 57'$ W. long., and is about eighteen miles long by eleven broad, with an area of 140 square miles. Surface mainly undulating and suitable for cultivation; but the extinct volcano, called the Souffrière, in the north, rises to a height of 3,700 feet, and the Morne à Garou to 4,000 feet. The road to the Souffrière is described as being embroidered with flowers, such as begonias and orchids, and groves of magnificent tree-ferns abound.

BOTANY.

Guilding, Lansdown. An account of the Botanic Garden in the island of St. Vincent, Glasgow, 1825. 4to, pp. 47, with three coloured views in the garden and a plan.

Report upon the Forests of St. Vincent. By E. D. M. Hooper, of the Indian Forest Department, Colonial Office, 1886.

Jacquin collected in St. Vincent, and the Rev. Lansdown Guilding made considerable collections of dried plants between 1820 and 1830 and transmitted them to Sir William Hooker; but as he was a zoologist rather than a botanist, it is probable that he did not exhaust the flora.

Grisebach describes twelve endemic plants, a larger number than known to him from all the rest of the chain of islands, excluding Dominica, from Tobago to Antigua.

Guilding's history of the foundation (1765) and progress of the botanic garden of St. Vincent is an interesting and valuable record. It was here

that Captain Bligh landed the best portion of his cargo of plants of the breadfruit early in 1793.

SANTA CRUZ (SEE ST. CROIX).

SOMBRERO.

A small island lying between Anguilla and the Virgin Islands. Nothing has been published on its vegetation.

ZOOLOGY.

Lawrence, G. N. Catalogue of Birds collected at the island of Sombrero, W. I., with observations by A. A. Julien. 'Ann. Lyc. N. Y.' viii. (1867), pp. 92-106.

34 species.

TOBAGO.

The most southerly of the windward group of the British West Indian Islands, lying in about 11° 9' N. lat and 60° 12' W. long., and about twenty miles from Trinidad. It is twenty-six miles long by

seven and a half broad, with an area of 114 square miles, and is mountainous and picturesque, the maximum elevation being 1,800 feet. There are no rivers nor streams navigable by even small boats, hence the virgin forest of the central mountain ridge remains intact. It is estimated that there are forty square miles of forest under valuable timber, and probably thirty under wood, of no great value except as fuel.

BOTANY.

Meyer, G. L. A Botanist's House in Tobago. 'Gardeners' Chronicle,' n. s. xiv. p. 456, with a view. A fragment.

Little is known of the botany, but that little points to a luxuriant if not a very varied flora. Mr. G. L. Meyer resided some months in the island, but he was only able to dry a few plants that grew near his dwelling; yet out of thirty-two species two or three at least were previously unknown.

ZOOLOGY.

TORTOLA (SEE VIRGIN ISLANDS).

VIRGIN GORDA (SEE VIRGIN ISLANDS).

VIRGIN ISLANDS.

A cluster of islands lying to the east of Porto Rico, between 18° to $18^{\circ} 50'$ N. lat. and $64^{\circ} 20'$ and $65^{\circ} 40'$ W. long. The principal islands are Vieques and Culebra belonging to Spain, St. Croix, St. Thomas, and St. Jan belonging to Denmark, and Virgin Gorda, Anegada, Jost Van Dyke, Tortola, and Peter's Island belonging to England. The area of the larger islands is only from sixteen to forty square miles, and the greatest elevations are 1,780 feet in Tortola and 1,550 feet in St. Thomas, St. Jan, or St. John, and Virgin Gorda being a little lower, whilst in the western Culebra and Vieques the hills are only 500 to 600 feet high. Anegada, as its Spanish name implies, is half submerged, or rather elevated only a few feet above the level of the sea.

St. Croix is much the largest island, and its natural history has been separately discussed and contrasted with that of the smaller and more contiguous islands (see p. 459).

Among the smaller named islands of this group are Cockroach, Savana, Tobago, Frenchman's Norman, Peter, Ginger, Guano, and Camanoe.

BOTANY.

Knox, J. P. An historical account of St. Thomas, W. I., with notices of St. Croix and St. John. New York. 1852. 271 pp.

The chapter on zoology is very slight and unimportant, though there is 'a complete list' of the plants of St. Thomas.

West, H. Bidrag til beskrivelse over St. Croix med en kort udsigt over St. Thomas, St. Jan, Tortola, Spanishtown og Crabeneiland. Copenhagen, 1793. 8vo. Vegetation of St. Croix and St. Thomas described, pp. 259–336.

Krebs, E. Bidrag til St. Thomas' Flora. 'Krøyer Naturhistorisk Tidsskrift,' ii. (1846–49), pp. 291–302.

Eggers, H. F. A. The Flora of St. Croix and the Virgin Islands. 'Bulletin of the United States National Museum.' Washington, 1879. 8vo, pp. 133.

Baron Eggers' enumeration is based mainly on plants from St. Croix and St. Thomas. He has 783 indigenous plants from the Virgin Islands, against 666 from St. Croix. There is almost no endemic element, and nearly all the plants are common to Porto Rico. *Eggersia*, Hook, f. (in Hook, Ic. Pl. t. 1401), a new genus of Nyctagineæ, discovered by Baron Eggers in the island of St. Thomas, is an interesting exception, so far as is known at present, but it may occur in Porto Rico.

Second Report on our Experimental Knowledge of the Properties of Matter with respect to Volume, Pressure, Temperature, and Specific Heat. By P. T. MAIN, M.A.

SINCE the first part of this report was written further investigations have been made on some elements and compounds with the view of determining the variations in vapour-density with rise of temperature, and the molecular weights of bodies.

Vapour-density Determinations.

In a paper contributed to the Royal Society of Edinburgh, July 18, 1887, Dr. A. Scott, using a modified form of V. Meyer's apparatus, described in a paper published in 1879,¹ obtains the vapour-densities, at high temperatures, of a number of elements and compounds, and deduces the molecular weights given below:—

Na, K, Hg, S₂, CsI, CsCl, RbI, RbCl, KI, AgCl, PbCl₂, MnCl₂, FeCl₂, CrCl₃, CdBr₂.

A table is given showing the theoretical numbers side by side with the experimental.

Vapour-densities of Nitric Oxide; and of Antimony.

In 1886² Mensching and V. Meyer found that zinc had, at very high temperatures, vapour-densities, such that Zn is the molecule of zinc, so that mercury, cadmium, and zinc all consist of monatomic molecules in the gaseous state; magnesium they did not succeed in volatilising; but with germanium, the boiling point of which is not far from that of zinc according to Winkler, they hope to be more successful.

In 1887³ they found that at a low temperature, viz., at 100°, nitric oxide has the same vapour-density (relative) as at higher temperatures, the contraction of the air in an air-thermometer and of the gas in a thermometer filled with nitric oxide instead of air being precisely the same, as the air and the gas were cooled equally.

In 'Chem. Soc. Trans.' 1887, p. 397, Dr. A. Richardson shows that, whereas the dissociation of nitric peroxide into NO₂ molecules is complete at 140°, a further dissociation of the NO₂ begins immediately at higher temperatures, and is completed at 620°, the products being nitric oxide and oxygen; the density at 620° being two-thirds that at 140°.

Mensching and V. Meyer,⁴ having found that at a white heat the vapour-densities approached those corresponding to the molecular weights P₂, As₂ for the elements phosphorus and arsenic, without, however, quite reaching the values required, found at the highest temperatures vapour-densities for antimony which were less than for the formula Sb₃; but, as they did not arrive at any temperature at which the coefficient of expansion and the vapour-density remain constant, they were unable to decide whether Sb₂ or Sb is the molecular weight of antimony.

⁴ *Ibid.* 20, 1887, p. 1833.

Vapour-densities of Aluminium Chloride.

Nilson and Pettersson¹ found for aluminium chloride at temperatures from 440° to 1260° vapour-densities varying from 7.789 to 4.277, the density decreasing very rapidly from 440° to 760°, and still diminishing regularly, till at about 1100° it remained nearly constant up to 1260°, the value between these temperatures being somewhat lower than that required by the formula AlCl_3 on account of the platinum of the apparatus being attacked by the chloride at these high temperatures. The result of their observations showed that at no range of temperatures at which the chloride was entirely gaseous was the formula Al_2Cl_6 applicable. They adopt, therefore, AlCl_3 as the formula.

Vapour-densities of Aluminium-ethyl and -methyl.

L. Roux and E. Louise² find, for aluminium-ethyl (boiling at 195°–200°), vapour-density 8.1 at 235°, 6.2 at 258°, 2.5 at 310° and at 350°. The first number corresponds to the formula $\text{Al}_2(\text{C}_2\text{H}_5)_6$, and the last to less than one-third of it. The authors conclude that the true formula is $\text{Al}_2(\text{C}_2\text{H}_5)_6$, and that the diminution of density is due to some cause unknown at present.

Again, the same authors³ find vapour-densities of aluminium-methyl by V. Meyer's method, obtaining 5.1, 4.75, 4.6, 2.4, 1.8 for densities at the temperatures 182°, 216°, 310°, 340°, 440°; the theoretical density of the vapour for the formula $\text{Al}_2(\text{CH}_3)_6$ is 5.02, which they consider to be approximately reached at 310°; as to the diminution of vapour-density at higher temperatures, they find that that is due to a decomposition of the compound into aluminium, olefines, and hydrogen.

At the end of a paper on some vapour-densities by W. Grünwald and V. Meyer,⁴ they say that Roux and Louise have given to aluminium-ethyl the formula $\text{Al}_2(\text{C}_2\text{H}_5)_6$ without, as seems to them, adequate proof; and that from investigations on aluminium-methyl they have come to the conclusion that no molecule with the formula $\text{Al}_2(\text{CH}_3)_6$ exists at any temperature.

Vapour-densities of Stannous Chloride and Cuprous Chloride.

Using a form of air-thermometer described by Goldschmidt and V. Meyer,⁵ Biltz and V. Meyer find the boiling-point of stannous chloride to be 606.1.⁶ For this compound V. Meyer had, in conjunction with C. Meyer, also with Züblin,⁷ found two molecular formulæ Sn_2Cl_4 and SnCl_2 for different temperatures. Biltz and V. Meyer, on making a fresh series of observations with very accurate determinations of the temperatures at which they were made, found that there was no range of temperature at which the vapour-density becomes constant, corresponding to a molecular formula Sn_2Cl_4 , but that the vapour-densities at

temperatures 639°; 678°; 699°; 759°·6; 790°; 1113°
are . . . 8.34; 8.57; 8.49; 8.26; 7.7; 7.08

¹ *Zeitschr. f. Phys. Chem.* 8, p. 459; *Ber.* 20, 1887, *Ref.* 623.

² *C. R.* 106, 73, 1888; *Ber. Ref.* 1888, p. 125.

³ *C. R.* 106, 602; *Ber.* 1888, *Ref.* 219.

⁵ *Ber.* 15, 1882, p. 141.

⁶ *Ber.* 21, p. 22.

⁷ *Ber.* 12, 1879, p. 1195; and 13, 1880, p. 811.

For Sn_2Cl_4 the density would be 13.06, and for SnCl_2 , 6.53.¹ The molecular formula for stannous chloride is inferred to be SnCl_2 .

The molecular formula Cu_2Cl_2 remains unaltered at the highest temperatures used by Biltz and V. Meyer.

Vapour-densities of Ferric Chloride.

Next appears a paper by Grünewald and V. Meyer,² in which these authors attempt to find the vapour-densities of ferric chloride at high temperatures with the view of deciding whether these indicate a molecule Fe_2Cl_6 at any temperature-range, and whether there is a molecule FeCl_3 . For this purpose they make a series of determinations at the temperatures of boiling sulphur, 448°, boiling phosphoric sulphide, 518°, and boiling stannous chloride, 606°. At the temperature of boiling sulphur the ferric chloride was volatilised slowly and completely, and its vapour-density, from the mean of four determinations—10.675, 10.559, 10.227, 10.487—was 10.487 at 448°; now the vapour-density for Fe_2Cl_6 would be 11.2, which is greater than this mean result and than either of the individual numbers. The authors say that determinations at even slightly lower temperatures are inadmissible, for the temperature of volatilisation must be very close to 448° (see Friedel and Crafts further on). At 518° they found 9.569 for the vapour-density as the mean of three determinations; but they found that even at this temperature about one-tenth part of the ferric chloride had been converted into ferrous chloride and chlorine, the ferrous chloride being much less volatile than the ferric; the vapour-density would be that of the ferric chloride remaining as vapour together with the chlorine.

At 606°, that is, by heating in the vapour of stannous chloride, the six experiments at this temperature gave a mean result 8.383; about one-eighth part of the ferric chloride was decomposed.

At about 750° in a Perrot's furnace the mean of three experiments gave 5.436; but here about a third of the ferric chloride was decomposed into ferrous chloride and chlorine.

At 1077° experiment gave 5.307; while at 1036° it gave 4.915, the larger number for the higher temperature being due to volatilisation of some of the ferrous chloride.

At about 1300° the numbers found by two vapour-density determinations were 5.155 and 5.115.

It is seen that no temperature at which the vapour-density was determined in the above experiments, in which ferric chloride was volatilised in an atmosphere of nitrogen, gave the vapour-density 5.6, corresponding to the formula FeCl_3 ; and in such experiments it is hopeless to expect it, as the ferric chloride at high temperatures is decomposed into chlorine and ferrous chloride; but, as the only conclusion which is consistent with their experiments, the authors infer that there is no molecule Fe_2Cl_6 , and that FeCl_3 is the only formula for ferric chloride.

Experiments in an atmosphere of chlorine do not modify this conclusion.

It is noticeable, however, that at about 448° the vapour-density is in some determinations over 10.6, while the formula Fe_2Cl_6 requires 11.2, which is but little larger. The possibility of the coexistence of Fe_2Cl_6

¹ *Beil.* 1888, p. 412; and *Nachr. d. kgl. Ges. d. Wiss.* Göttingen, 2, 1888, p. 19.

² *Ber.* 21, 1888, p. 687.

molecules with FeCl_3 molecules at temperatures above the volatilisation-point of ferric chloride is, therefore, an hypothesis for which there appears at present to be no sufficient experimental proof; but the cases of acetic acid and nitric peroxide are somewhat similar, and in the latter case Ramsay has by Raoult's method found,¹ besides the formula NO_2 at high temperatures, that there is a formula N_2O_4 for low temperatures, although the vapour-densities at low temperatures above the boiling-point are always intermediate between those required by the two formulæ.

Vapour-densities—Friedel and Crafts.

In Crafts' study relative to the vapour-density of iodine² he showed that, contrary to the opinion of V. Meyer at that time, the results got by V. Meyer's process must differ from those by Dumas' process, where in the former process the vapour-density can vary with the tension i.e., vapour-pressure (of the iodine), as well as when there is dissociation. Thus, in V. Meyer's process it is generally conceived that the substance which is volatilised in the vapour-pressure cylinder acts by forming a more or less dense layer of vapour at the bottom of the cylinder, which, expanding rapidly, acts like a piston in expelling a quantity of (generally) nitrogen, the volume of which at the high temperature employed is equal to that of the expanded vapour. If, however, the temperature is very much above the boiling-point or the volatilising-point of the substance vapourised, the conditions are different, the vapour *diffusing* to a considerable extent in the space occupied by the nitrogen; in this case there is no longer reason to expect that the volume of the nitrogen expelled measures the amount of the substance volatilised in the manner contemplated by V. Meyer's method.

Troost³ had found a variety of different densities of iodine-vapour at 400° , and at pressures varying from 768 mm. to 34.52, these densities varying from 8.70 to 7.35, the density corresponding to I_2 compared with air being 8.8; and attributed these results to a deviation from Gay-Lussac's law of dilatation.

Now Crafts admits a difference of the vapour-density due to reduction of vapour-pressure by diffusion, the diffusion having the effect of increasing its volume, diminishing its pressure, and thus bringing it nearer to the state of a gas considerably above its boiling-point at the reduced pressure, and more nearly to the state of a perfect gas; the results of Crafts and Meier in one set of experiments for iodine were obtained by a modification of Dumas' method, the globe being filled partly with air, partly with vapour of iodine, the vapour-pressure of the iodine in some of the experiments being a tenth of an atmosphere. In correctly calculating from the experimental results the densities of iodine-vapour, account has to be taken of the deviation of iodine from Boyle's and Gay-Lussac's laws; but Crafts and Meier⁴ found that at the reduced pressure the rate of dilatation from 355° upwards was the same as that of air. The vapour-densities (referred to air at the same pressure and temperature) at still higher temperatures were attributed by him to a gradual dissociation, the rapidity of which was increased by diminished pressure, as happens in the case of Friedel's hydrochlorate of methyl oxide, and as shown by Lemoine for HI .

¹ *C. S. J.* 1888, 621.

² *C. R.* 91, 1880, p. 54.

³ *C. R.* 92, 1881, p. 39.

⁴ *C. R.* 92, 1881, p. 39.

Acting on the principle which Crafts and Meier had used for iodine-vapour, Friedel and Crafts¹ obtained for aluminium chloride, by acting under diminished pressure, a range of comparatively low temperatures (218° to 433°), during which this body had a coefficient of dilatation nearly the same as that of air—not deviating more than CO₂ does. By the modification of Dumas' process they found vapour-densities throughout this range of 215 degrees varying between 8·31 and 9·93, the higher and lower values being indiscriminately scattered through this temperature-range. Now the value which Deville and Troost² had found was 9·35, corresponding to Al₂Cl₆; and Friedel and Crafts found this to be practically constant from 218° to 433°. Within this range, therefore, they assume that Al₂Cl₆ is not dissociated into molecules AlCl₃.

No fewer than twenty-one determinations were made for determinations of vapour-densities within these limits of temperature.

Thus, though Nilson and Pettersson have proved that AlCl₃ is the molecule at very high temperatures, it is proved that aluminium chloride at lower temperatures can exist in the gaseous state as made up of Al₂Cl₆ molecules.

The same authors (Friedel and Crafts³) find that ferric chloride in an atmosphere of chlorine was not dissociated at 440°, no deposit of crystallised ferrous chloride being visible even at that temperature. Having determined the densities of chlorine gas at different temperatures, and its coefficient of dilatation, they used this as the gas with which vapour of ferric chloride was made to mix in the modification of Dumas' method. The results deduced by them for the vapour-density of ferric chloride between 321°·6 and 442°·2 were as follows:—

temperatures	321°·6 ; 325°·2 ; 356°·9 ; 357° ; 442°·2 ; 442°·2
densities . .	11·41 ; 12·47 ; 12·04 ; 11·85 ; 11·66 ; 11·30

The number for Fe₂Cl₆ is 11·25.

Again, the same authors⁴ find for gallium chloride (B.P. 215°) in the same way 11·73 at 237°; Lecoq de Boisbaudran had found 13·4 at 247°, and 11·9 at 273°; the theoretical density for Ga₂Cl₆ is 12·2, which holds approximately from about 237° to 273°; the boiling-point is about 215°: hence between these temperatures gallium chloride is Ga₂Cl₆, which at higher temperatures dissociates into GaCl₃ molecules.

Friedel and Crafts remark that Al₂Cl₆, Ga₂Cl₆, In₂Cl₆ are more readily dissociated into the smaller molecules the higher the atomic weight of this group of metals.

Vapour-densities of Sulphur—Biltz.

Finding that the tendency of investigations on vapour-densities is apparently to give simpler molecules to some compounds, such as aluminium chloride, to which Deville and Troost had given the formula Al₂Cl₆, and to replace the formula Sn₂Cl₄ by SnCl₂, Fe₂Cl₆ by FeCl₃, Biltz undertakes⁵ to examine sulphur with the view of deciding whether its vapour-densities give at any temperature-range the formula S₆, and whether they confirm the formula S₂ at higher temperatures. For this purpose he uses the form of apparatus which had been used by Grüne-

⁵ *Ber.* 21, 1888, p. 2013.

wald and V. Meyer for ferric chloride, and makes determinations at the temperature of boiling stannous chloride, 606° , which give a mean value 3.6. Now Dumas and Mitscherlich¹ had found—Dumas for temperatures 506° to 524° values 6.512 to 6.581 nearly constant during interval of temperature 18° ; Mitscherlich 6.9 at 508° (?); the very wide difference between these results and 3.6 for vapour-density of sulphur at a temperature not very far removed, and the insufficiency of Dumas' and Mitscherlich's proof of S_6 , their temperature interval being much too small—these considerations led Biltz to determine, at the temperature 518° of boiling phosphoric sulphide, the density by Dumas' method; this gave, as a mean result of several nearly agreeing determinations, the value 7.0. By the same method he obtained a nearly constant value 4.7 at 606° in vapour of boiling stannous chloride.

The values by Dumas' method were constant in different determinations at the same temperature, and gave higher results than those given by V. Meyer's method of replacement by nitrogen.

Biltz made a series of experiments by the nitrogen-displacement method at the same temperature 518° , but varying the amount of the substance, and obtained (p. 2016) a series of thirteen results, in which, while the amount of substance varied from .1067 gram to .0450 gram, the density found varied regularly from 7.104 to 4.509. These results are due, according to Biltz, to the greater or less dilution of the vapour of the substance with nitrogen, the observed density being less the less the amount of substance, and thereby the more the amount of dilution.

He brings forward as instances of this effect of dilution Horstmann's experiments² on acetic acid, Meier and Crafts on the densities of vapour of iodine,³ and V. Meyer and C. Langer's⁴ experiments with bromine vapour. Moreover he himself confirms this explanation by making vapour-density determinations by Dumas' method, but leaving in the vapour-density vessel a mixture of nitrogen with sulphur vapour, and obtaining thus, at the same temperature, different values for the vapour-density of sulphur, as before. By experiments by Dumas' method in a series of vapour-densities at intervals from 467.9° to 606° , nearly equally divided among ten determinations, results were obtained varying from 7.937 to 4.734; but these gave no constancy for vapour-density corresponding to S_6 through any range of temperature, as may be seen from a graphic representation of the results.

By varying the method used and by making a series of observations over a considerable range of high temperatures he finds constant results only for S_2 .

Biltz continued his investigation into the influence of the size and shape of the vessel on vapour-density determinations;⁵ and in another article⁶ he has described a new method of taking the vapour-densities of volatile chlorides.

The method consists in heating the metal in an atmosphere of chlorine, and thus forming the chloride by absorbing chlorine, the amount of which by volume is either equal to, greater than, or less than, the volume of the product according to the volume of chlorine in the molecular

weight of the chloride; the change of volume of the chlorine (if any) was measured by a method first used by Crafts.

In the other paper mentioned Biltz discusses the effect of using smaller and smaller quantities of substance with larger vessels in vapour-densities in reference to cases in which at the same temperature different values are obtained, due either to dissociation, or to expansion towards the perfectly gaseous state.

Vapour-density of Hydrofluoric Acid.

Gore has found that the volume of hydrofluoric acid obtained by passing hydrogen over heated silver fluoride was, when measured at about 100° , twice that of the hydrogen which went to form it; hence that the formula of hydrofluoric acid is HF, where F is 19; but that at lower temperatures the volume of hydrofluoric acid diminished rapidly with diminution of temperature in comparison with the hydrogen.¹

Mallet determined the density of hydrofluoric acid at 30.5° , and found it to correspond to the molecular weight 39.32 at that temperature, nearly the number for H_2F_2 .²

Thorpe and Hambly³ find that at fourteen temperatures ranging at short intervals between 26.4° and 88.3° the densities correspond to molecular weights ranging from 51.19 at 26.4° to 20.58 at 88.3° , there being no range of temperatures corresponding to a formula H_2F_2 ; they therefore consider the case similar to that of acetic acid, and that the only molecular formula is HF.

The vapour-density determinations by Nilson and Pettersson, by V. Meyer in conjunction with others which have just been referred to, of sulphur by Biltz, of nitric peroxide by Ramsay, of hydrofluoric acid by Thorpe, of aluminic, ferric, and gallic chlorides by Friedel and Crafts, have had for one of their objects that of ascertaining whether certain supposed more complex formulæ assigned to an element or a compound could be maintained on investigation in cases where the body in the state of gas at higher temperatures was known to consist of simpler molecules. In some of the cases the answer from experiment has been that there is no longer reason from vapour-densities to believe in the more complex molecular groupings, as in the case of sulphur; while in other cases, *e.g.*, iodine, nitric peroxide, there seems no room to doubt that the body exists in two distinct states, in one of which the gas or vapour consists of molecules of half the mass of the molecules of the body in the other state; to this case there may be added the case of the chlorides examined by Friedel and Crafts. Acetic acid and nitric peroxide have some similar characters in reference to the vapour-densities of the *saturated* vapours from their liquids, and to the behaviour of equal volumes in relation to pressure and temperature, as shown by Ramsay and Young; and it remains to be seen whether acetic acid does not consist at low temperatures of molecules in which are combined two of the molecules of acetic acid at moderately high temperatures.

In the case of bodies which are dissociated by heat the dissociation is gradual, and in general although not always the temperature-range from the beginning to the end of the dissociation is considerable; this seems to be the distinguishing feature of bodies undergoing dissociation, and

¹ *Phil. Trans.* 1869, p. 173.

² *Amer. Chem. Journ.* 3, 1881, p. 189.

³ *C. S. J.* 1888; *Trans.* p. 765.

is exhibited in the case of iodine, whose two-atom molecules undergo by heat dissociation, which is gradually brought to completion after passing through more than 300° under ordinary conditions.

When bodies in the state of vapour are heated and found to have, not far from their boiling-points, vapour-densities corresponding to definite molecular weights, we have in by far the majority of cases no dissociation, and these are the molecular weights of the compounds; the contrast between these cases and the preceding is in the short temperature-range from the boiling-point at which a constant (relative) vapour-density has been arrived at.

It is the force of general considerations such as these that makes one hesitate, in cases such as that of sulphur, antimony, aluminium chloride, ferric chloride, in which the simpler formulæ S_2 , Sb_2 (?), $AlCl_3$, $FeCl_3$ are not attained until a temperature has been reached very far above the volatilising or boiling-point, before assuming that we are simply dealing with vapours which do not attain the approximately gaseous state for an extraordinarily long interval above the temperature at which they boil or volatilise.

Although positive proof may be absent of the existence of more complex molecules, it may be that at intermediate temperatures there exists, mixed with the simpler molecules, a larger proportion of more complex molecules as the temperature sinks from the point at which the simpler molecules exist alone.

The alternative to some such supposition is that Gay-Lussac's law, as a purely physical law, has a few recently discovered very remarkable exceptions in the case of bodies, some of which have not very high boiling or volatilising points; that certain bodies, in fact, expand for a very long range of temperatures much more rapidly than Gay-Lussac's law requires.

In the Bakerian Lecture, May 1887, Professor J. J. Thomson gives an account of the effect of passing the electric discharge, by sparks or by the silent discharge, through the vapours of iodine, bromine, nitric peroxide, and chlorine. An abstract of this paper is given in the 'Proc. Roy. Soc.' 42, 1887, p. 343. Among the results obtained is that in a tube exhausted of air and containing vapour of iodine, maintained at a temperature 214° the vapour-density of the iodine is diminished from 130 ($H=1$) to 84; this result, which was a permanent change, lasting at least for several hours, was produced by direct heating by Crafts and Meier at a temperature estimated by them at 1400° .¹ The effect of sparking bromine vapour is transient, but while it lasts produces a considerable increase of pressure, due, as Professor Thomson thinks, to a transient dissociation of bromine molecules. The vapour-density determinations in these experiments 'showed that bromine vapour is dissociated if it is heated for a long time at a low pressure, even though the temperature is not very high.' He makes the remark—which seems to be of great importance, in determinations of vapour-densities, in all cases where molecules may be undergoing dissociation—that 'for experiments on vapour-density the gas should be maintained at a constant temperature for some time before the experiments are made.' The neglect of this precaution may not unlikely account for a number of discrepancies between different experimenters, or the same acting under

¹ *C. R.* 90, 1880, p. 690.

different conditions, in respect of the temperatures corresponding to vapour-densities.¹

In the case of iodine the striking feature is the fact that it can remain for some considerable time at ordinary temperatures in a state in which a large proportion of the two-atom molecules are dissociated.

In the first part of their report, p. 22, 1886, experiments with solid and liquid benzene by W. Fischer² were alluded to, from which Fischer constructed curves for the vapour-pressures at different temperatures in the neighbourhood of the melting-point of solid benzene; but the curves for solid and liquid benzene did not, as they should, meet at the melting-point of the solid.

Ramsay and Young have since shown³ that Fischer's experimental results were sufficiently accurate, but the construction of his curves was at fault; for the curves could not be accurately drawn from the formulæ he used. On calculating the constants in a Biot's formula $p = a + ba^t$, the calculated results were more nearly than those found by Fischer's formula in agreement with his experimental results; and in particular near the melting-point Fischer's recalculated numbers are found to be in close accordance with Ramsay and Young's; indeed, the agreement is so close as to afford a strong presumption of the purity of the benzene used in both cases.

Specific Heat and Temperature.

When a mass m of a body is raised from temperature t_1 to temperature t_2 , under given conditions, the amount of heat consumed in the process being Q , the quantity $\frac{Q}{t_2 - t_1}$ is called the mean capacity of the mass for heat between those temperatures; for example, if t_1 be 0° and $t_2 = t^\circ$, then Q/t is the mean capacity for heat between 0° and t° of the mass m of the given body under the conditions. If, now, for all temperatures from 0° to beyond t , Q should be found to be proportional to t , then Q/t is the capacity for heat of mass m of the body for each degree from 0° to t° , where t is any temperature whatever within the limit; but if, as is in general the case, Q/t varies as t varies, then this ratio gives no information as to the capacity for heat for the various temperature-intervals between t_1 and t_2 , but gives for the whole interval t_1 to t_2 the mean heat-capacity of mass m .

The mean capacity for heat for *unit mass* for interval δt , called the mean specific heat, is $\frac{1}{m} \frac{\delta Q}{\delta t}$, where δQ is the heat consumed in raising the temperature of mass m of the body under the given conditions from t to $t + \delta t$; and, as the capacity for heat increases usually with the temperature, and the expenditure of heat on a body will in general raise its temperature, we have generally a limit value $\frac{1}{m} \frac{dQ}{dt}$ for the capacity for heat between t and $t + \delta t$ when δt has become indefinitely small.

This quantity $\frac{1}{m} \frac{dQ}{dt}$ is the specific heat of the body at t° under the given conditions; if δt is 1° , $\frac{1}{m} \frac{\delta Q}{\delta t}$ is undistinguishable from $\frac{1}{m} \frac{dQ}{dt}$,

¹ See first part of this report, 1886, pp. 18 and 40. ² *Wied. Ann.* 38, 1886, p. 400.

³ Physical Society, Dec. 11, 1886; and *Phil. Mag.* Jan. 1887.

the specific heat being sensibly constant for an interval of one degree. When no mass is mentioned unit mass is understood.

The conditions referred to above may be various as to pressure and volume of the body, but in practice only two are necessary to discuss, viz., (1) when the body is kept at constant pressure, *e.g.*, that of the atmosphere; (2) when the body is kept, or reckoned as kept, at constant volume.

The necessity for taking account of these two conditions is most obvious in the case of bodies in the state of gas or vapour, the change of volume of bodies in the liquid and solid conditions being comparatively small; but as the liquid and the gaseous states merge one into the other, there are circumstances in which the change of volume cannot be neglected in the case of bodies in the liquid state.

Experiment enables the mean capacity for heat to be determined from 0° C. to t° C., giving a numerical value for Q/t . A number of similar determinations may be made for other temperatures; referring the results to unit mass of the body we thus get a number of mean specific heats between 0° and t_1° , 0° and t_2° , 0° and t_3° , and so on. From a sufficient number of such determinations, if the intermediate temperatures t_1° , t_2° , . . . are fairly uniformly distributed between 0° and t° it is possible to find an interpolation formula $Q/t = C_0 + at + bt^2 + \dots$ for the heat-capacity of the body between 0° and t° , where t is any temperature between 0° and the extreme limit of temperature in the set of experiments. Hence we can deduce the specific heat of the body at any such temperature; for, for unit mass, $\frac{dQ}{dt}$ is this specific heat; if we call this

C_0 at 0° and C at t_1° we have, $Q = C_0t + at^2 + bt^3 + \dots$; whence dQ/dt (or C) $= C_0 + 2at + 3bt^2 + \dots$

This is the principle of the method by which from experimental results formulæ are obtained, giving approximately the specific heat of a body for a range of temperatures more or less extended, from 0° C., and from which curves can be drawn representing the relation of specific heat to temperature in the case of each body.

It is evident, from what has been said, that it is not always a matter of indifference what temperature is chosen at which to compare solid bodies, simple or compound, as to specific heat; for, although for most solids the temperature is not required to be known accurately, the variation in specific heat being very slow, in others the variation of this with the temperature is sufficient to make it a matter of importance whether the specific heat used be that at ordinary, or at lower, or higher temperatures.

For the present this part of the subject may be dismissed, to be reconsidered later on.

Specific Heats—Solids.

In the introduction to a series of memoirs on this subject, Regnault¹ says that although the subject had been attacked by many physicists before Dulong and Petit, it is to these last, with the exception of some very careful and accurate experiments by Lavoisier and Laplace, that we are indebted up to his time for any accurate determinations of the heat-

¹ *Ann. Chim.* (2), 73, 1840, p. 5.

capacities of bodies, and in which the principal causes of error incidental to such delicate experiments had been obviated.

Dulong and Petit—Elements.

In their great work on the laws of cooling, published in the 'Jour. de l'Ecole Polytech.' tome xi., Dulong and Petit gave determinations of specific heats between 0° and 350° and showed that the specific heats of bodies in general increase with rise of temperature; examples of this are given also in 'Ann. Chim. Ph.' (2), 7, 1818; as an example, among others, the mean heat capacity of iron

	between 0° and 100°	=	1098
"	0	" 200	= 1150
"	0	" 300	= 1218
"	0	" 350	= 1255

This gives a fair idea of the general rate of increase of specific heat of metals and other solid bodies generally with rise of temperature. Dulong and Petit in a subsequent paper¹ enunciate the following law: '*The atoms of all simple bodies (elements) have exactly the same capacity for heat.*' This law is arrived at by multiplying the specific heats of a number of elements in the solid state, viz., Bi, Pb, An, Pt, Sn, Ag, Zn, Te, Cu, Ni, Fe, Co, S, by their atomic weights; it is true that the products so obtained were not exactly the same for each element, but this deviation was attributed by these physicists to errors arising from two sources—the determination of the specific heats, and the analyses from the results of which the then received atomic weights were deduced. And this law was not restricted by them to bodies in the solid state alone, but was supposed to apply to bodies in the liquid and gaseous states. This opinion was supported by the specific heats of oxygen and nitrogen gases as determined by de Laroche and Berard, and of hydrogen; the number for the last gas they find somewhat too small, but consider that the determination of its specific heat was vitiated by an error which de Laroche and Berard had overlooked. In the number given by Dulong and Petit the atomic weights were referred to that of oxygen taken as unit, and the specific heats to that of water.

Neumann's Law for Compounds.

In 1831 Neumann published² a set of determinations of specific heats of minerals, and attempts to apply to them the principle of Dulong and Petit's law; to find, in fact, if there exist any simple relations among their molecular heats corresponding to what Dulong and Petit had apparently established as to the atomic heats of elements. He includes in his determinations, however, some elements, and finds that arsenic and antimony are, or seem to be, exceptions to the law of atomic heats. Noticing that these crystallise in forms not belonging to the regular system, the doubt occurs to him whether the specific heat is independent of crystalline form, and whether it is the same for substances of the same chemical composition but crystallising in different systems. This doubt is, however, set at rest by his observation that calc spar and aragonite have the same specific heat, and similarly in other cases of dimorphism.

¹ *Ann. Chim.* (2), 10, 1819, p. 405.

² *Pogg. Ann.* 23, 1831, p. 1.

By examination of a number of well-known minerals he arrives at the following general conclusion: 'The specific heats of bodies of similar chemical composition are inversely as their stöchiometric quantities.' As examples the following are adduced: calc spar, CaCO_3 ; bitter spar $(\text{CaMg})\text{CO}_3$; magnesite $(\text{MgFe})\text{CO}_3$; spathose iron ore, FeCO_3 ; and calamine, ZnCO_3 . These are bodies of similar chemical composition; the stöchiometric quantities are the quantities found thus (taking, for example, magnesite): find the value assigned to CO_3 , according to the atomic weights of C and O, and add the amounts of magnesium and iron according to the proportions of these metals found on analysis of the mineral.

The product of the specific heat and the stöchiometric quantity is found to be approximately the same for all the above minerals. Similarly for the minerals heavy spar, anhydrite, celestin— BaSO_4 , CaSO_4 , SrSO_4 —also for magnesium-, mercuric-, zinc-, cupric-, calcium- oxides; for cinnabar HgS , realgar AsS , lead glance PbS , blende ZnS ; and for ferric oxide, minium, chromic oxide, in the case of each of which he remarks that two [stöchiometric] parts (antheile) are combined with three of oxygen.

The above examples are reproduced here principally to show in what sense Neumann meant the words 'similar chemical composition' to be applied.

Regnault's Determinations¹—Elements and Compounds.

In his first memoir² Regnault deals with solid elements, making fresh determinations of those examined by Dulong and Petit, and on which they founded their law, and in addition finding the specific heats of a number of elements which they had not determined; on pp. 61–64 of this memoir he gives a table of his results. Comparing the atomic weights with that of oxygen as 100, the atomic weights of the elements examined by him vary from 200 to 1400, while the atomic heats vary only from 38 to 42, with the exception of that of carbon, which is too small unless its atomic weight is doubled; he halves the then received atomic weight of silver, thereby bringing it in harmony with the law and bringing the formula of its sulphide from that adopted before (AgS) to Ag_2S , whereby the isomorphism of this sulphide with cuprous sulphide is represented by giving to the two similar formulæ. With the exception of carbon and possible exceptions of a few elements of which he had not at the time pure specimens in sufficient quantity, including boron and silicon, Regnault concludes that Dulong and Petit's law applies to the elements generally with fair approximation, but not with accuracy, even allowing for experimental errors. He expresses the opinion that possibly their law may be true quite rigorously if each element were examined at a definite point of the thermometric scale appropriate to it, and if the specific heat were obtained free from admixture with the heat which is used up in expanding the body, and if the body is at a temperature so far removed from the temperature of fusion that no portion of the heat of fusion enters into the observed number representing the specific heat.

In his second memoir³ on the specific heat of simple and compound

¹ Regnault, *Ann. Chim.* 2, 73, 1840, p. 5; 3, 1, 1841, p. 129; 9, 1843, p. 322; 3, 38, 1853, p. 129; 46, 1856, p. 257; 63, 1861, p. 5; 67, 1863, p. 427; 4, 3, 1864, p. 495; 7, 1866, p. 450.

² *Ann. Chim.* (2), 73, 1840, p. 5.

³ *Ibid.* (3), 1, 1841, p. 129.

bodies Regnault discusses the question which Neumann had raised in 1831 and applies to it all the resources of his experimental skill, not confining himself to natural minerals as Neumann had done, but using a variety of compounds prepared pure in the laboratory. A number of alloys examined by him gave heat-capacities equal to the sum of those of their component parts in most of the twelve cases he gives; but in some cases in which the alloy was fused or near its fusing-point at the higher temperature, the specific heat calculated on this supposition differed considerably from the observed. He then examines a large variety of oxides, sulphides, chlorides, bromides, iodides, fluorides, nitrates, chlorates, phosphates, metaphosphates, pyrophosphates, arseniates, sulphates, chromates, borates, tungstates, silicates, carbonates; each of these sets—*e.g.*, oxides—he divides into series, each series having a like chemical formula, that is, corresponding to the same general formula, as RO representing the series of oxides PbO , HgO , MnO , CuO , NiO , MgO , MgO ; R_2O_3 representing the series Fe_2O_3 , As_2O_3 , Cr_2O_3 , Sb_2O_3 , Bi_2O_3 , Al_2O_3 , the numbers of each series being compared among themselves as to their specific heats and formula-weights. Among the protoxides the product of the specific heat and the formula-weight is nearly the same as a rule, but there are two exceptions—oxide of magnesium and oxide of zinc. Among the sesquioxides the same general rule holds good for what we will call the molecular heats, with the exception of alumina, in the form of corundum especially, which has a far lower molecular heat than the other sesquioxides. These apparently exceptional cases Regnault explains by a difference in the state of aggregation of these oxides. Another difficulty is the case of iron pyrites, which has the same formula RS_2 as stannic sulphide but a much lower molecular heat; this Regnault explains by saying (p. 191) that there is no analogy between these two sulphides, while bisulphide of molybdenum, which has a molecular heat not very different from that of stannic sulphide, presents, he says, some resemblance to it in physical constitution. Regnault here seems to recognise that it is not sufficient that the formulæ should be similar and the bodies belong to the same series; it is necessary also that the formulæ should, as it were, not be accidentally similar, but be similar as representing also bodies of the same class.

Although Regnault finds that calcite and aragonite do not differ in their molecular heats, he finds that the specific heat of chalk and of saccharoid marble are about the same and markedly higher than the other forms. Regnault sums up the general result of this memoir thus: 'In all compounds of similar atomic composition and chemical constitution the specific heats are inversely as the ['atomic'] molecular heats'; and he gives the same reasons for the fact of this law being only approximately true, as in the case of elements.

In further communications on the specific heats of solids Regnault finds by direct determination that of potassium, cooled by contact with solid CO_2 and let fall into a calorimeter containing naphtha, and shows that if the then accepted atomic weight of potassium is halved, this new atomic weight is in accordance with Dulong and Petit's law; and this new atomic weight separates potassium from the alkaline earth metals and other metals in the state of oxidation RO , with which metals in fact potassium¹ has no relations of isomorphism; that ordinary phosphorus

¹ *Ann. Chim.* (3), 26, 1841, p. 261.

has a specific heat rapidly rising with the temperature, the mean between -78° and $+10^{\circ}$ being $\cdot 1740$, and between $+10^{\circ}$ and $+30^{\circ}$ being $\cdot 1887$; that solid mercury has between -78° and -40° a mean specific heat $\cdot 3192$; that of solid bromine between -78° and -9° is $\cdot 087$, and between -78° and -20° it is $\cdot 082$, the melting-point of bromine being taken to be not lower than -9° . [As a fact, the melting or the solidifying point of bromine has been the subject of a considerable number of determinations, and the temperature has been estimated by different experimenters at points varying from $-7\cdot 2^{\circ}$ to -25° ; the most recent values and the most trustworthy, however, are about $-7\cdot 2^{\circ}$.]

It is seen that mercury and bromine in the solid state obey the law of specific heat, while the atomic heat of phosphorus is somewhat small. The specific heat of *red* phosphorus¹ is only slightly less than that of ordinary phosphorus, the difference being perhaps due to the remoteness of red phosphorus from its melting-point. The two varieties are considered by Regnault to have a difference which is inconsiderable.

It will be noticed that the specific heat is always greater at higher than at lower temperatures.

In two subsequent papers Regnault² makes determinations of various metals, including those accompanying platinum, cobalt, and nickel whose specific heats he finds nearly equal; manganese, magnesium, which all fall into line with Dulong and Petit's law; sodium (by surrounding the tube containing the metal with a freezing mixture at -34°), attributing to it half the then accepted atomic weight by which change sodium is found to be in complete accord with the law; lithium chloride, from which he found that the molecular heat was only slightly less than that of sodium chloride, which was slightly less than that of potassium chloride, from which facts he infers that lithium chloride must have a similar atomic composition to these others, thus halving the atomic weight of lithium to make the formula of lithium chloride LiCl (instead of LiCl_2). In confirmation of this view he says (t. 46, p. 278): '*For bodies of the same chemical composition the product of the specific heat by the molecular weight is smaller the smaller the molecular weight.*' Thus for RCl_2 —e.g., CaCl_2 and BaCl_2 —the molecular heats are $114\cdot 72$ and $116\cdot 44$; again each of these numbers is quite different from those for R_2Cl_2 , as Li_2Cl_2 , Na_2Cl_2 , K_2Cl_2 , which are $148\cdot 09$, $156\cdot 97$, $161\cdot 19$. For aluminium he finds the atomic heat somewhat smaller than for most of the others.

Just as in the case of the two varieties of phosphorus, so he finds for the vitreous and metallic varieties of selenion examined at low temperatures sensibly the same specific heat agreeing well with Dulong and Petit's law, and mentions the fact (t. 46, p. 288) that the vitreous and porcelain modifications of arsenious oxide have the same specific heat; but remarks on the unexpected result that the enormous evolution of heat accompanying the transformation of vitreous into metallic selenion has no appreciable effect on the specific heat of this body; a similar result he obtains afterwards for silicon (t. 63). By direct determination he afterwards obtains a specific heat for lithium, which agrees with the formula LiCl , and includes lithium among the elements conforming to Dulong and Petit's law. For boron and silicon he tries, by using a different atomic weight for each from that then used, to place these

¹ *Ann. Chim.* (3), 38, 1853, p. 129.

² *Ibid.* (3), 46, 1856, p. 256; and 53, 1861, p. 5.

elements among those to which the law of atomic heats applies, but without success.

It is noticeable that Regnault, finding so large a number of elements conform to the law of specific heats, is at last disinclined to admit any exception for elements in the solid state, and is only deterred from doubling the atomic weight of carbon with the object of including this element by finding how widely the values of the specific heats¹ differ from one another for carbon from different sources.

The constancy of specific heat in spite of allotropic variations of the body examined, as mentioned above, is disputed by Bettendorf and Wüllner² for selenion and for arsenicum; but for the former one may prefer Regnault's result, and the latter is perhaps open to criticism. A marked exception is, no doubt, the case of diamond, the specific heat of which is much less—between 100° and 0°—than that of other varieties of carbon. The highest temperature in Regnault's experiments on the specific heats of solid bodies was 100° or, in a few cases, a few degrees higher; generally it was lower than 100°, and much lower in cases where the fusing-point of the body was low.

Woëstyn's Law of Molecular Heats.

In 1848 Woëstyn³ enunciated the following law as to the specific heats of compounds: 'If C is the specific heat and A the formula-weight of a compound of certain elements, the atomic weights of which are a_1, a_2, \dots and the specific heats c_1, c_2 , and if n_1, n_2, \dots be the number of atoms of each element in the formula of the compound, then $AC = n_1a_1c_1 + n_2a_2c_2 + \dots$ '

It is taken as a fact by Woëstyn that different elements have different atomic heats—that a_1c_1, a_2c_2, \dots are not all equal; and, therefore, as an accident if the molecular heats of compounds of similar atomic composition are equal or approximately so. Thus it follows from his principle that lead sulphate and calcium sulphate should have different molecular heats, the difference being that between the atomic heats of lead and calcium; it also follows from his principle that there should be the *same* difference between the molecular heats of the carbonates, of the protoxides, of the nitrates, chlorides, bromides, iodides, chlorates . . . of this pair of metals; and similarly for any other pair of metals which form salts and oxides of similar atomic composition.

By taking the differences between the known molecular heats of an oxide of lead and corresponding sulphide, and so for mercury and for bismuth, and antimony for the same amount of combined oxygen, he finds numbers which according to his law should be equal, being the difference in each case between the atomic heats of sulphur and oxygen, and which are, in fact, nearly equal. The law, tested by a considerable number of compounds, is found to give results very fairly in accordance with it.

Extension of Dulong and Petit's Law to Compounds.

Although Neumann, and after him Regnault, showed most interesting relations among molecular heats of compounds, from which Regnault

¹ *Ann. Chim.* (3), 1, 1841, p. 204.

² *Pogg.* 133, 1868, p. 293; and *Ann. Chim.* (4), 14, 1868, p. 476.

³ *Ann. Chim.* (3), 23, 1848, p. 296.

had in fact been able to deduce the atomic weights of elements which were not at the time capable of examination as to their specific heats directly, as in the cases of Rb, Cs; of Li; of Sr, and Ba; by means of the rule that the molecular heats of bodies of similar atomic composition and chemical constitution are equal; no rule had been found by which the molecular heats of compounds were connected with the atomic heats of the component atoms; with the exception of Woëstyn's law (1848) that the molecular heat is the sum of the atomic heats for all the atoms in the molecule. But this exception was indeed important (1) for the frank recognition of the fact that the atomic heats of elements cannot be reckoned as equals—at the best as varying within narrow limits; in fact, as putting forward as of fundamental importance that Dulong and Petit's law is only approximate and not a very near approximation; (2) for the extension to compounds generally of the rule which Regnault had found to apply to alloys. But Woëstyn's law led to no important results, as it was not followed up by a determined attempt to confront the questions, what are the atomic heats which must be assigned to elements such as chlorine, oxygen, hydrogen, nitrogen, fluorine, and others, the specific heats of which in the solid state cannot be determined directly; and of carbon, the specific heat of which in the free state at ordinary temperatures varies so much with its state of aggregation and in allotropic modifications of it. The number of compounds which contain one of these elements or more is so very large a proportion of the compounds to which the rule should be applied, and by means of which it should be verified, that it is not to be wondered at that no important generalisation resulted from it. To Woëstyn, however, must be given the credit of giving definite expression to an idea which Hermann Kopp independently took as the basis of his great work on the subject.

Garnier in 1852¹ proposed, as did Cannizzaro in 1858,² the following relation: if C be the specific heat of a compound, n the number of atoms, and A the molecular weight, then $\frac{AC}{n}$ is constant.

Kopp's Investigations on Specific Heats.

Hermann Kopp was among the first to draw the attention of chemists to the relation of physical properties of compounds to chemical composition; as early as 1841 he first stated his law of boiling points of homologous series of carbon compounds. The very existence of such a law-like relation struck many chemists as paradoxical; so axiomatic had seemed to them the assumption that the properties of elements are extinguished when these enter into combination that the regularity of the effect on the boiling-point of the addition of one atom of carbon and two of hydrogen to the molecule of a compound was combated at first, but has long been accepted in principle universally; other investigations with a similar object by H. Kopp need not be mentioned here. His work on specific heats of bodies in the solid state was part of this general plan, and his object in it was to find if possible a relation between the specific heats of compounds and of their component elements. With this object he made a large number of determinations of specific heats of elements, and of compounds prepared in the laboratory, as also of a number of minerals;³ and

¹ *C. R.* 37, p. 130.

² *Il Nuovo Cimento*, 7, p. 321.

³ *L. Ann. Supplement*, b. 3, 1864, p. 1; and *loc. cit.* p. 289.

showed how nearly the molecular heats calculated according to his theory agreed with those observed chiefly by himself and by Neumann, Regnault, and Pape. The principle of Kopp's theory is that each element in combination has the same atomic heat as when free in the solid state at such temperatures that both the element and the compound are so far removed from their melting-points that they may be considered to approximate to the state (if one may use the expression) of 'perfect' solids; for most of the elements the atomic heat is known by direct experiment; in other cases, according to Kopp, a value can be assigned to the atomic heat such that the molecular heats calculated by assuming it for compounds of this element shall agree well with those found by direct experiment, the molecular heat of a compound being thus supposed to be independent of its constitution, but dependent only on the number and specific heats of the elements composing it. As an example of his method of finding on his theory a theoretical specific heat of an element in the solid state take the case of oxygen; for oxides of the formula RO , where R is the atom of copper, magnesium, and a number of other metals whose atomic heats are for each not far from 6.4 which is the average value, Kopp finds the molecular heats of all, including for each the results of several experimenters, and calculates for all a mean value 11.1. Subtracting from this 6.4 the remainder 4.7 is the atomic heat of oxygen as deduced from the molecular heats of those oxides. Similarly for oxides of the general formula R_2O_3 he gets the mean molecular heat 27.1. Now, as R includes metals, all of which are shown to have atomic heat about 6.4, and the average atomic heat is 6.4, three times the atomic heat of oxygen $= 27.1 - 12.8 = 14.3$; and the atomic heat of oxygen, as deduced from these oxides is 4.8. Other values obtained in a similar way are 3.7, 4.1, 4.2, 4.0, 3.4, 3.9. From all the separate values Kopp deduced an average of 4.0 for the atomic heat of oxygen; for that of sulphur and of phosphorus, 5.4; fluorine, 5; silicon 3.8; boron, 2.7; hydrogen, 2.3; and carbon, 1.8. For the rest of the elements in general, including the well-known metals except beryllium, together with nitrogen and bromine, he gives the atomic heat 6.4.¹

Specific Heats of Carbon, Boron, and Silicon—Weber.

Among the exceptions to Dulong and Petit's law, Kopp was obliged to admit carbon, boron, and silicon. Weber² was struck by the agreement of several experimenters as to the fact of the specific heats of different forms of carbon being unlike, and the atomic heats calculated from them having different values; and on comparing the temperatures within which Regnault, De la Rive, and Marcet, Kopp, Wüllner, and Bettendorf obtained their numbers for charcoal, gas-carbon, natural graphite, blast-furnace graphite, and diamond, he noticed that although for each form the different observers got different numbers, there was this peculiarity, that the lower numbers for each form of carbon always corresponded to lower temperatures: for example, the mean specific heat found by De la Rive and Marcet for diamond was .1146, the range of temperature being 3° to 14°; and that found by Regnault was .1469, the range being 8° to 98°.

On investigation Weber found that the specific heat of this substance, carbon, increases more rapidly than that of any other substance with rise of temperature, the specific heat of diamond near 200° being three times as great as it is near 0°. In order to get correct values of the specific heat

¹ *Loc. cit.* p. 329.

² *Ber.* 5, 1872, p. 303.

of diamond between 0° and 200° , he finds the mean heat-capacity of diamond at twelve nearly equal intervals between 0° and 200° , and thus finds the constants in an equation of the form, $C'_0 = a + bt - ct^2$ to represent the mean heat-capacity between 0° and t° ; whence the specific heat at t is $a + 2bt - 3ct^2$. Similarly he finds for graphite an equation of the form, $\gamma_t = a + bt$ for specific heat at temperatures between 0° and 100° .

Dewar by an experiment in which varieties of carbon were successively heated by an oxyhydrogen flame on a bed of quicklime, using a water-calorimeter, found a mean specific heat $\cdot 42$ up to a temperature of about 2100° ; which would give an atomic heat of about 5 at some temperatures very much higher than 200° . This shows that a temperature can be reached at which the specific heat of carbon gives an atomic heat not much less than that required by Dulong and Petit's law.

Previously Dewar had found¹ a mean value of the specific heats of varieties of carbon between 20° and 940° , the temperature of boiling zinc; this mean specific heat was $3\cdot 2$.

Weber in 1874² continued his researches on the specific heats of varieties of carbon, and found results from a large number of experiments, from which he was able to deduce specific heats of diamond at a variety of temperatures up to nearly 1000° , the determinations of the specific heats of other forms of carbon being made at temperatures under 250° , at which their specific heats began to approach that of diamond closely. Weber's determinations showed that in reference to specific heat the forms of carbon other than diamond behave alike, but differently from diamond at the lower temperatures.

In accordance with what is known with regard to the relation of specific heat to temperature generally, there is no point at which it ceases to increase with rise of temperature; and although the true specific heat of a solid body will not be given at any temperature at which it begins to soften or to approach its liquid state, in the case of carbon there is no such danger; for the temperature at which it tends to soften or become liquid is so high that we cannot suppose that we are in the neighbourhood of it at 1000° . An inspection of the curve in Weber's paper of 1874, taken in conjunction with the curves of variation of specific heats of metals alluded to later on, will suggest that it is possible, by taking temperatures higher and higher by hundreds of degrees, to arrive at results in excess of the specific heat demanded by Dulong and Petit's law. The temperatures at which Dulong and Petit's law holds good for metals are not temperatures at which the specific heat is constant, but at which it varies steadily and slowly; and if this is the case, as it is for metals generally at ordinary temperatures, the specific heats are such as are in accordance with Dulong and Petit's law; this is a general result of experiment, but in the case of metals, which still at higher temperatures have specific heats increasing steadily above 100° as they do between 0° and 100° , experience does not warrant us in using the specific heats at higher temperatures (see Pionchon's results further on). The case of carbon has been shown by Weber to be entirely different from that of the metals, for at ordinary temperatures the specific heat increases with rise of temperature very much more rapidly; but after the temperature has been raised sufficiently high the specific heat at higher temperatures increases only moderately with rise of temperature, and carbon reaches the steady state

¹ *Phil. Mag.* 4, 44, p. 461.

² *Jahresb. f. Chem.* 1874, p. 64; and *Ann. Chim.* 5, 1876, p. 7.

in this respect, in which it is comparable with the general rule in respect to metals. Now this temperature, as is well seen in the diagram, is reached by diamond at 600° : and therefore if we are not arbitrarily to choose a temperature at which the specific heat will be such that the atomic heat of carbon is 6.4, the range of temperature within which we should determine the specific heat to test the conformity of carbon with the law of Dulong and Petit should not much exceed 900° , at about which temperature the specific heat is .45: this would give atomic heat of carbon 5.4.

By experiments with crystallised boron and crystallised silicon Weber found that the specific heats of both increased rapidly as the temperature rose, the specially rapid variation ceasing for silicon before 100° ; the atomic heat of silicon being 5.63 at 184° , and 5.74 at 300° . In the case of boron the specific heat rose rapidly up to 230° , and there is no result given to show at what temperature it becomes nearly constant. Moreover, the crystallised boron is not pure, always containing aluminium, as Hampe has shown.¹

It may be remarked that in respect of the relation of Dulong and Petit's law to the molecular heat of compounds at ordinary temperatures, Kopp finds that this relation is best expressed by taking the low atomic heats of carbon 1.8 rather than the value which more nearly agrees with Dulong and Petit's law.

Beryllium ;—Humpidge ; Nilson and Pettersson.

The specific heat of beryllium between 10° and 100° was found to be .47, from which the atomic weight 13.6 was deduced by applying the law of atomic heats. The impossibility of finding a place for a metal with this atomic weight in the classification of elements in the periodic system led chemists to doubt the accuracy of this specific heat, especially as the metal from which the specific heat was got was known to be not free from impurity. With the object of settling this point the late Professor Humpidge devoted a great amount of labour to preparing beryllium in a state as nearly pure as he could; and he succeeded in preparing some with not more than 0.8 per cent. of impurity.² He proceeded to make a great number of determinations of specific heats at various temperatures, and found that beryllium, like carbon, silicon, and boron, has a specific heat which rapidly increases with rise of temperature, and becomes nearly constant at temperatures above 400° , from that to 500° increasing quite slowly. The number .5403 within those limits when multiplied by 9.1 gives 5.64, which is not far from that required by the law of Dulong and Petit. Now analyses of the chloride and bromide had shown that, if their formulæ are BeCl_2 , BeBr_2 the atomic weight is 9.1; whereas the formulæ BeCl_3 , BeBr_3 correspond to atomic weight 13.6. Humpidge published a further paper³ giving details of his work on the specific heat, and of his determinations of the vapour-densities of the chloride and bromide, confirming that got by Nilson and Pettersson for the chloride.

The results of Humpidge were partly anticipated by Nilson and Pettersson in respect of the rapid increase of specific heat of the element,

¹ *L. Ann.* 183, 1876, p. 75.

² *Proc. Roy. Soc.* 38, 1884, p. 188; *Abs. C. S. J.* 1885.

³ *Proc. Roy. Soc.* 39, 1885, pp. 1-19.

in papers published by these authors in 1880.¹ But Humpidge worked without knowledge of this, and the general result thus obtained independently is conclusively established.

Nilson and Pettersson recently made² a series of determinations, in a new improved apparatus, of the vapour-densities of the chloride of beryllium at temperatures from 490° to 1500°, and found that above 680° the vapour-density remains constantly of the value corresponding to the formula BeCl_2 ; the vapour-densities for the chloride and the bromide mentioned before as determined by Humpidge led to the same result as to the atomic weight of beryllium, giving the formulæ BeCl_2 and BeBr_2 .

Specific Heats at Different Temperatures.

The variation of specific heat with temperature was investigated by Bède³ for certain metals; he found that the specific heat between 0° and t° was sufficiently accurately expressed by the formula $c = k + at$, in which k and a are constants depending on the nature of the metal. The results are given in the following table:—

Copper	$k = \cdot 0910$	$a = \cdot 000023$
Iron	$= \cdot 1053$	$= \cdot 000071$
Lead	$= \cdot 0286$	$= \cdot 000019$
Tin	$= \cdot 0500$	$= \cdot 000044$
Zinc	$= \cdot 0865$	$= \cdot 000044$

The smallness of the fractions a shows how slow the increase of specific heat is with rise of temperature.

This, as Pionchon's investigations show, can only hold for moderate ranges of temperature.

Pionchon. Specific Heats at High Temperature.

Pionchon⁴ finds expressions for the total heat-capacities and the specific heats at temperatures from 0° to 1100° and over for the metals silver, tin, iron, nickel, cobalt, giving formulæ for these physical quantities for various high temperatures and wide intervals of temperature.

Thus, for silver, from 0° to 907°:—

$$Q = \cdot 0578t + 0\cdot 544t^2 + 0\cdot 6t^3;$$

whence

$$c = \cdot 0578 + 0\cdot 588t + 0\cdot 718t^2;$$

also for 907° to 1100°;

$$Q = \cdot 0748t + 17\cdot 20;$$

whence

$$c = \cdot 0748;$$

making for silver a nearly constant specific heat between 900° and 1100°.

Similarly for iron he finds the specific heat constant at $\cdot 218$ between 720° and 1000°; and again at $\cdot 1987$ between 1050° and 1200°.

For silver at 0° specific heat is $\cdot 05758$, and at 900° it is $\cdot 08008$.

Iron has at 0°, 600°, 660°, 700° specific heats $\cdot 11012$, $\cdot 19956$, $\cdot 2442$, $\cdot 32433$. These examples illustrate the great increase in specific heat as the temperature rises through hundreds of degrees in the case of these metals, and the increase is very striking in the case of iron, seeing that at the highest

¹ Ber. 13, 1451, 1784.

² Ann. Chim. 6, 9, 1886, p. 554.

³ Mém. couronnés par l'Acad. Roy. de Belg. 27, 1855, p. 1.

⁴ C. R. 103, 1886, p. 1122; Ann. Chim. 6, 1887, p. 1133.

temperature quoted the metal is very far from its melting or softening point; there is in fact, as these experiments, taken as a whole, show, a gradual increase in specific heat, which at three or four hundred degrees would remove the metal from the state with respect to specific heat required by Dulong and Petit's law.

He finds that silver melts at 907° , and that its specific heat before and after fusion is the same.

As in the case of silver, so in the case of iron, Pionchon refers the absorption of heat and almost constant specific heat of iron at two temperatures to some change of state in iron at those temperatures; and he thinks this idea confirmed by changes, at the neighbourhood of those temperatures, of the sign of the specific heat of electricity of iron observed by Thomson and by Tait.

Tin melts at quite a low temperature, about 230° ; 232.7° as found by Person;¹ and may be heated to a high temperature without volatilising. Thus Pionchon was able to make a thorough investigation into the specific heat of *liquid* tin from 232.7° to 1110° .

This investigation in respect of metals and Weber's on the specific heats of carbon constitute the greatest advance in our knowledge of the variation of specific heat of bodies in the solid state that has hitherto been made; for hitherto we had to be content with determinations made, as those by Dulong and Petit, and afterwards by Bède, at temperatures up to no higher than 350° .

The calorimetric method which Pionchon used is founded on Pouillet's principle² of determining the temperature of a ball of platinum by means of an air-thermometer, and the specific heat by letting the ball drop into a water-calorimeter of sufficient depth. A formula was thus obtained by Pouillet applicable to temperatures up to 1200° for the specific heat at any temperature t ; thus total heat-capacity of platinum between 0° and t° , or

$$q_0 = .03237t + .000041t^2;$$

whence

$$c = .03237 + .000082t$$

gives the specific heat at t° by the air-thermometer.

Violle subsequently, in 1887, adopting Pouillet's method, found specific heats of platinum and other metals, using a more accurate air-thermometer than Pouillet's;³ his more accurate results for platinum were

$$q_0 = .0317t + .000006t^2;$$

whence

$$c = .0317 + .000012t,$$

which is an equation from which t can be found when c is known.

Pionchon in this memoir finds the melting-point of silver to be 907° as against the temperature found by Violle, viz., 954° , which is much too high.

The Specific Heat of Water.

The specific heat of water is required in the determinations of temperatures by the use of the platinum ball and the water calorimeter; this was found by Regnault⁴ to be $1 + .00004t + .0000009t^2$ for temperatures between 0° and 230° by the air-thermometer.

¹ *Jahresb. f. Chem.* Fittica, 1847.

² *C. R.* 3. 1836, p. 782.

³ *C. R.* 1877, p. 543; 1878, p. 981; 1879, p. 702.

⁴ *Mém. de. l'Acad.* 21, p. 729.

J. Bosscha gives¹ a formula $c=1+0.0022(t-18)$ as giving more accurate values, as he thinks, for the specific heat of water at various temperatures than Regnault's.

Neesen² found, as some other observers before him had found, that the specific heat of water diminishes from 0° up to a temperature as to which they are not agreed, and increases after that temperature. If this is so it is an exception to the otherwise almost invariable rule of increase of specific heat with rise of temperature.

According to some recent experiments by Cardani and Tomasini³ the mean specific heat of liquid water below 0° *diminishes* with rise of temperature, being, *e.g.*, .985 between -10.67° and 0°, and .953 between -6.52° and 0°.

In a paper by Professor Rowland on the mechanical equivalent of heat, presented to the American Academy of Arts and Sciences, June 11, 1879, the author shows how, by assuming the axiom that the heat equivalent to a definite quantity of energy is definite and constant, and repeating Joule's experiments, using a large range of temperature of the water in the calorimeter, the heat-capacity of water between two temperatures can be determined so as to enable the specific heats at various temperatures within those limits to be known, approximately. By this method, as also by the method of mixtures, referring the temperatures to Sir W. Thomson's absolute scale, Rowland was able to deduce the conclusion that the specific heat of water decreases through 4° to about 30° to 35°; a temperature at which it is a minimum, and above which the specific heat of water as usual increases with rise of temperature without change of the state of the water.

Carbon Compounds—De Heen.

Several organic compounds, organic acids and salts of organic acids in particular, gave, as found by P. de Heen,⁴ specific heats which varied considerably with the temperature below 100°; this may possibly be due to the temperatures being too high in these cases—or in most of them—to give specific heats corresponding to the truly solid condition as suggested by H. Kopp,⁵ the body being more or less softened by the heat. A similar caution had been mentioned by Regnault, who looked upon a *portion* of the latent heat of fusion as being added to the true specific heat in many cases, and in part accounting for the deviation of specific heats from the law of atomic heats. It was on account of an incipient softening effect of heat near 90° on the 'vitreous' modification of selenion⁶ that Regnault compared the specific heat of this modification with that of 'metallic' selenion at low temperatures, *e.g.* -20°.

Other Specific Heats.

Naccari⁷ gives a formula $\gamma=a(1+bt)$ for the specific heat at temperatures from 0° to over 200° for the metals copper, antimony, silver, cadmium, aluminium, lead, zinc, nickel, and iron; as an example,

Pogg. Ann. 1874; *Jubelbd.* 549. ² *Wied. Ann.* 2, 18, 1883, p. 369.

Nuovo Cimento (3), 21, 185; *C. S. J. Abs.* 1888, p. 102.

Bull. Acad. Roy. Belg. (3), 5, 1883, p. 757; *Ber.* 16, 1883, p. 2655.

Ber. 19, 1886, p. 817.

⁶ *Ann. Chim.* 3, 46, 1856, p. 286.

R. Acc. di Torino, 23, 1887, p. 22; and *Beibl.* 12, 1888, p. 326.

for silver, a is $\cdot 05449$, and $b = \cdot 0003929$; so that ab , which is the coefficient of t , is $\cdot 0000184$.

And for copper, $a = \cdot 09205$; $b = \cdot 0002308$; and the specific heat of copper is

$$\cdot 09205 + \cdot 000021252t;$$

which agrees with Bède's

$$\cdot 0910 + \cdot 000023t$$

so far as Bède carried his approximation.

Quite recently Pionchon has made determinations¹ on the specific heat of quartz up to 1000° , and finds that it increases rapidly up to 400° from $\cdot 1737$ to $\cdot 305$; that from 400° to 1000° it remains remarkably constant. Now the molecular heat during this interval within which the specific heat of quartz is so nearly constant is $60 \times \cdot 305 = 18\cdot 3$; and this is $3 \times 6\cdot 1$, so that at these temperatures silica in the form of quartz has a molecular heat which corresponds to Cannizzaro's rule.

In reference to this Kopp quotes, from a memoir which he published in 1879,² a passage in which he says that it is not unlikely that the molecular heats of *compounds* of elements, which at ordinary temperatures have atomic weights not in accordance with Dulong and Petit's law, may possibly when raised to higher temperatures be so increased as to be in accordance with Garnier and Cannizzaro's rule, and that compounds, which are exceptions of Neumann's law as to the molecular heats of compounds of like atomic composition, may in this way come into accordance with it; although it is often impossible to realise the conditions required on account of approaching the fusing-point of the body, or exceeding the temperature at which the compound begins to decompose.

Kopp remarks that the molecular heat $18\cdot 3$ for SiO_2 , not only gives a result $3 \times 6\cdot 1$ nearly in accordance with Garnier and Cannizzaro's rule, but approaches nearly to the numbers for compounds of the formulæ XCl_2 , XBr_2 , XI_2 ; which are found by his experiments to vary between this number and $19\cdot 0$; and at the high temperatures of Pionchon for quartz this compound ranges itself among the compounds to which Neumann's rule applies.

The elements which are at ordinary temperatures exceptions to Dulong and Petit's law, so far as is known at present, are elements with small atomic weights, including sulphur, with atomic weight 32. The metal magnesium, with atomic weight 24, has a normal atomic heat; while that of aluminium, atomic weight 27, is low, about $5\cdot 7$; and that of beryllium, atomic weight $9\cdot 1$, is among the exceptions, the atomic heat being about 4; but the specific heat of beryllium varies immensely between 0° and 400° .³

Specific Heat—Liquids.

The specific heat of many liquids was found by Regnault⁴ for various temperatures; these were found always to increase with rise of temperature; but no general relation could be found connecting specific heats of bodies in the liquid state with molecular weights, temperature, or dilatation. In the liquid state the considerable internal, as well as some external, work complicates the expression, the dilatation, in fact, in the

¹ *C. R.* 106, 1888, p. 1344.

² *Ber.* 12, p. 896.

³ See Humpidge, *Proc. Roy. Soc.* 1885.

⁴ *Mém. de l'Acad.* t. 26, pp. 262–295.

case of liquids being rapid, so that the internal work becomes a very important part of the whole heat consumed in raising the temperature.

Recently Schiff has studied the specific heats of liquid organic compounds,¹ and has determined the specific heats of liquid hydrocarbons, alcohols, acids, and ethereal salts at different temperatures, and arrives at the following results among others: All ethereal salts of fatty acids, of the formula $C_nH_{2n}O_2$, have the same specific heat at the same temperature, being represented by the formula $K = .4416 + .00088t$. Again, following Van der Waals' method for finding points of comparison for bodies in the liquid or gaseous state, he finds the critical temperature by the rule laid down by Pawlewski² for the same ethereal salts—that their critical temperatures are to be found by adding 182.3 to their boiling-points at 760mm. Schiff divides the distance of the critical temperature from the absolute zero into 100 equal parts, which he calls critical degrees, and finds that *equal volumes* of these liquids have the same heat-capacity at the same critical degree.

Specific Heat. Gases and Vapours.

We will now consider the case of specific heats of bodies in the state of gas or vapour.

Gay-Lussac³ gave an account of some experiments for determining specific heats of gases at *constant pressure*, and concluded that the specific heats (or heat-capacities) of equal volumes of bodies in the gaseous state were equal; but further investigations by himself and a number of other physicists made it soon appear that the problem was more complex than was supposed, and that variations of temperature are of vital consequence.

It was not until Regnault undertook his investigations that any satisfactory collection of experimental results was obtained. From 1840 onwards Regnault occupied himself, among other physical and chemical investigations, with the subject of specific heats of bodies in the solid, liquid, and gaseous states. The work on this subject in respect of the gaseous state is part of the vol. xxvi. of the 'Mém. de l'Acad. des Sc.'

Regnault's Results for Gases and Vapours.

The following results were obtained by Regnault for atmospheric air at atmospheric pressure approximately constant:—

Between	30° and +10°	.	.	0 ... +100°	0 ... +200°
Specific heat	0.23771	.	.	0.23741	0.23751

hence the specific heat of air between 0° and 200° (for a certain nearly constant pressure, viz., atmospheric pressure) is independent of the temperature and = 0.2375. The temperatures were those of an air-thermometer.

For *oxygen* two experiments gave 0.21627, 0.21876, or a mean value 0.21751 for the specific heat between 7° and 200°. To compare the heat-capacities of equal *volumes* of oxygen and air, 1.10563 being the specific gravity of oxygen (air = 1), we have 1.10563×0.2175 to 0.2375, or 0.2405 to 0.2375 as the ratio of the heat-capacities. Thus the heat-capacity of a volume of oxygen at 760 mm. and a temperature between

¹ *L. Ann.* 234, p. 300; *C. S. J. Abs.* 1887, p. 6.

² *Ber.* 15, p. 2460; *C. S. J. Abs.* 1883, p. 276.

³ *Mém. d'Arcueil*, t. i. 1807, p. 180.

0° and 200° is greater than, but very little different from, that of the same volume of air under the same conditions.

And, for *nitrogen*, the heat-capacity between 0° and 200° is about the same as that of the same volume of air or of oxygen, for atmospheric air consists mainly of nitrogen and oxygen.

For *hydrogen* between about 0° and 200° the specific heat was found in four experiments to be:—

3.4196 3.4042 3.4108 3.4014

of which the mean value is 3.4090 for specific heat of hydrogen under the conditions of atmospheric pressure and any temperature between 0° and 200° . For low temperatures, as between 10° and -30° , Regnault got a mean value 3.3996, agreeing fairly with the value for higher temperatures. As in the case of oxygen, so here, multiplying the four results by 0.0692, the specific gravity of hydrogen (air = 1), the mean of the results compared with 0.2375 is the heat-capacity of hydrogen gas compared with that of an equal volume of air; this is 0.2359 to 0.2375; thus the heat-capacity of hydrogen is sensibly the same as that of an equal volume of air, the experiments giving for hydrogen a very slightly lower value.

On the above results Regnault remarks that air and gases, which at ordinary temperatures obey Boyle's law, are equally expanded by equal increments of temperature up to temperatures as high as and higher than 300° ; and that, as shown above, the heat-capacity of air is the same for equal temperature-intervals independently of the initial temperature as measured by the dilatation of air (by an air-thermometer); and, as the same constancy is observed in the case of other gases which obey Boyle's law, shall we not, he asks, be led to admit that the air-thermometer indicates temperatures in a manner proportionally to the quantities of heat which it receives? (p. 109.)

The above and a few other of Regnault's results are tabulated below:—

	Specific heat	Heat-capacities of equal volumes
Air	0.2375	0.2375
Oxygen	0.2175	0.2415
Nitrogen	0.2368	0.2438
Hydrogen	3.4090	0.2359
Hydric chloride	0.1845	0.2333
Carbon monoxide	0.2450	0.2370
Nitric oxide	0.2321	0.2406
Chlorine	0.1210	0.2964
Carbon dioxide	0.2169	0.3307
Nitrous oxide	0.2262	0.3447

In the case of the first seven of the above gases the specific heat remained constant up to 200° , and these seven are gases which very approximately obey Boyle's law. It is to be remarked that in the case of these the heat-capacities of equal volumes are very nearly equal at atmospheric pressure.

In the case of chlorine, and still more of carbon dioxides and nitrous oxide, the heat-capacities of equal volumes vary with the temperature, the values for a given range of temperature being less the lower the mean temperature of the range and increasing as this temperature rises up to 170° in these experiments; the specific heats therefore increase

with rise of temperature. Regnault (p. 129) remarks that this increase of specific heat with rise of temperature is probably true of all gases the elasticity of which deviates much from Boyle's law.

Volatile Liquids—Regnault.

The specific heats of vapours of volatile liquids were determined by Regnault, by experiments described in this memoir, in which the total heat was directly given which was yielded by the body in the state of vapour in passing from the temperature of the vapour to the temperature of the calorimeter, in which the liquid was condensed: this heat consists of the heat-capacity of the vapour from the highest temperature taken to the temperature of condensation *plus* the heat given off at this temperature by the mass of vapour in becoming liquid *plus* the heat given out by the liquefied vapour in passing from this temperature to the temperature of the calorimeter. Thus the heat-capacity of the vapour as such between two temperatures is not given by any one experiment. Regnault endeavours to get rid of the two unknown quantities of heat simultaneously by eliminating them between two different experiments, in the one the temperature of the vapour being lower than in the other; in each experiment the weight of the liquid condensed is found, as also the difference between the highest temperature of the vapour and the temperature of the calorimeter, whence can be calculated the total heat given out by *unit weight* of the substance in passing from the temperature of the vapour at starting to the temperature of the calorimeter. Now the results of the two experiments differ in respect of the initial temperature of the vapour and the final temperature of the liquid in the calorimeter; the initial temperature in one of the experiments is taken as high as conveniently can be, and the final temperatures are reduced to 0° by adding to the total heat in the case of each experiment the total heat-capacity of the liquid between the temperature of the calorimeter (say about 8° to 20°) and 0° . This last is a comparatively small *correction* for each experiment, and the *difference* only of these corrections enters into the result. For the result is obtained by subtracting the corrected result of one experiment from that of the other, the difference being the total heat-capacity of the *vapour* between the initial higher temperatures of the pair of experiments. Dividing the number thus got by the interval of temperature, the quotient is the mean specific heat of the vapour between these temperatures.

In addition to the bodies in the list given above, Regnault obtained results for heat-capacities of equal volumes of the following gases and vapours: marsh gas, olefiant gas, sulphur dioxide, ethyl chloride, hydric sulphide, ammonia; and the vapours of water, ether, alcohol, carbon disulphide, benzene, oil of turpentine, methyl alcohol, ethyl cyanide (propionitril), ethyl bromide, ethyl sulphhydride, ethyl acetate, acetone, ethene dibromide, chloroform, bromine, silicon chloride, phosphorous chloride, arsenious chloride, titanous chloride, stannous chloride. As the result of the whole series of experiments on the bodies chosen, Regnault comes to the conclusion that there is no *general relation* of the specific heat and molecular weights of bodies in the state of gas or vapour corresponding to Dulong and Petit's law as to elements in the solid state.

Specific Heat and Pressure.

In the cases of atmospheric air, hydrogen, and carbon dioxide, Regnault found by experiments at several atmospheres' pressure, *e.g.*, for air 12·4 atmos., no observable difference in the specific heat of unit mass due to pressure, but that this is not the case for chlorine, at least at ordinary temperatures, and is probably only true for bodies at temperatures at which they conform to Boyle's law.

Specific Heat of Elements in the Gaseous State.

He concludes¹ that the law which had been announced by several physicists, 'that simple bodies (elements) in the state of gas had identical specific heats (heat-capacities) of equal volumes,' can only be considered as an 'ideal law,' applicable to bodies which had quite uniform laws of compressibility and dilatation (obeying Boyle's and Gay-Lussac's laws exactly), and therefore not applicable to bodies as we actually know them in the state of gas.

Specific Heats of Liquids—Regnault.

From experiments on a number of bodies, *viz.*, water, bromine, alcohol, ether, carbon disulphide, methyl alcohol, acetone, ethyl sulphide, ethyl chloride, ethyl bromide, ethyl cyanide, ethyl acetate, chloroform, ethene dibromide, benzene, oil of turpentine, silicon chloride, phosphorous chloride, arsenious chloride, stannic chloride, titanous chloride, of which the specific heats in state of vapour were determined, Regnault determined the specific heats in the liquid state, and found that the mean specific heat of each body in the state of gas is always less than in the liquid state, especially when compared at about the same range of temperature; and that in the case of several of the bodies the former value is only a small fraction, less than half, of the latter. Hence, he says, there cannot exist a rigorous law connecting specific heats of bodies with their atomic (or molecular) heats alone, for the specific heats vary, as he has shown, with change of temperature and of state.

It must here be mentioned that Joule² published the results of three experiments on the specific heat of air, the mean of which gave 0·2296; these are noticed by Regnault.³

Specific Heat at Constant Volume—Regnault.

The experimental results given by Regnault are obtained in every case by finding the amount of heat given to the calorimeter by a gas or vapour parting with heat either at atmospheric pressure or at some constant, or nearly constant, pressure greater than atmospheric. The problem of finding the specific heat of a gas or vapour, the *volume* of which is not allowed to vary, is solved by applying the principles of thermodynamics to the results for constant pressure. Through the ranges of temperature within which Regnault worked, the following gases alone were found to have specific heats independent of temperature and of pressure, so far as the effect of pressure was determined: oxygen,

¹ *Mém.* xxvi. p. 309.² *Phil. Mag.* vi. p. 143.³ *Mém.* xxvi. p. 40.

nitrogen, hydric chloride, carbon monoxide, nitric oxide; bodies which, as gases, show a remarkable conformity to Boyle's and Gay-Lussac's laws in respect of the variation of volume with compression and dilatation; for such bodies the heat-capacities of equal volumes at *constant pressure* were found to be nearly the same, the smallest value being 0.2333 for hydric chloride, and the largest 0.2438 for nitrogen.

If we can assume for each of these gases that a volume of it experiences no change of temperature as a consequence of expansion into a vacuum—that therefore no *internal* work is employed in the act of expanding—the specific heat at *constant volume* can be calculated from that at constant pressure in each case by calculating the thermal equivalent of the external work done by the expansion of 1 gram of the gas from 0° to 1° against the pressure of the atmosphere and subtracting this result from the specific heat at constant pressure; the remainder is the specific heat at constant volume.

From this can easily be deduced the heat-capacity of a litre of the gas at constant volume by multiplying the specific heat of (a gram of) the gas by the gram-weight of a litre of it; the result so obtained as the heat-capacity of a litre of air at constant volume is 0.218; and the difference would be the same for each of the gases mentioned if its changes of volume by compression and dilatation accurately followed Boyle's and Gay-Lussac's laws, and if the internal energy suffered absolutely no change. The actual result in each case is only approximate and subject to varying amounts of error, due to the greater or less deviation of the above suppositions from accuracy within the conditions of the experiments.

The approximate specific heat of air at constant volume is .1685; at constant pressure .2375, the difference .0690 being the heat equivalent of the external work done by one gram of air against atmospheric pressure under the conditions.

Again the specific heat of hydrogen at constant pressure being 3.408, that at constant volume is 2.415, the difference being .993 which is the equivalent of the work done by the expansion of 11.16 litres (the volume of 1 gram of hydrogen at 0° and 76 cm.) against the atmospheric pressure 76 cm. during the rise of temperature of this volume of hydrogen from 0° to 1°.

The heat-capacity of 2 grams (or 22.32 litres under the same conditions) of hydrogen is therefore 6.816 at constant pressure, 4.830 at constant volume, the difference being $2 \times .993 = 1.986$.

The appended table gives the specific heats at constant pressure and at constant volume of 22.32 litres of a number of gases referred to 0° and 76 cm., calculating that at constant volume from that at constant pressure as above.

	At constant pressure.	At constant volume.
Hydrogen	6.846	4.830
Nitrogen	6.826	4.840
Oxygen	6.960	4.974
Hydric chloride	6.769	4.783
Carbon monoxide	6.860	4.874
Nitric oxide	6.951	4.965
Chlorine	8.591	6.605
Ammonia	8.643	6.657
Methane	9.488	7.502
Ethylene	11.312	9.326

In the above table it will be noticed that the first six gases have

nearly identical heat-capacities (of 22.32 litres) whether at constant pressure or at constant volume; and these are the gases for which Regnault found that the specific heats did not vary much with variation of pressure or of temperature; they also obey the laws of Boyle and Gay-Lussac very well. Of the remaining four, chlorine deviates more than the others from agreement with the laws mentioned; while ammonia behaves in accordance with these laws, and methane does not deviate much; but the heat-capacity of a given volume of ammonia is very different from that of an equal volume of either of the first six gases in the table, as also are those of the gases methane, ethylene, chlorine, and others; while the heat-capacities of equal volumes of vapours of a large number of liquids examined were still farther removed from those of the same volume of the six gases mentioned in the table; of which the heat-capacities of equal volumes are equal to that of air within 1 per cent., with the exceptions of oxygen and nitric oxide, in which the difference is just above 1 per cent. and of hydric chloride in which the difference is a little less than 2 per cent. Now the aberrations of chlorine and ammonia from the rule of constant heat-capacities of equal volumes of bodies in the gaseous state are, as seen by comparison with the six gases, glaringly wide; the rule does not hold even approximately for chlorine and ammonia. The deviations of these two gases from conformity with Boyle's and Gay-Lussac's laws seem an inadequate explanation; in the case of ethylene, again, the rule of heat-capacities entirely fails. This rule is therefore not supported by these wide investigations of Regnault.

E. Wiedemann on Specific Heats of Gases.

E. Wiedemann¹ repeats a number of Regnault's experiments on these specific heats, with improved apparatus and methods, and with a modification which in the case of vapours avoids condensation in the calorimeter, so that the specific heat of the vapour is determined directly in *one* experiment and not by the difference of two experiments, as in Regnault's method; the results differ slightly from Regnault's and are probably more accurate, but go no nearer to finding any general law. The chief addition made by Wiedemann is the determination of the variation of specific heat with temperature in the case of a considerable number of gases and vapours. With reference to the hint thrown out by Regnault, as to the possibility of an ideal law applicable to ideal gases, and corresponding to Dulong and Petit's law for solids, Wiedemann finds the true specific heats of various gases, including nitrous oxide, carbon dioxide, and ammonia, and finds that the specific heat of ammonia varies less with the temperature than either of the other two, while it approaches more nearly to a perfect gas in its elasticity or in its conformity with Boyle's law. Thus Regnault gives² for $p v / p' v'$, where p' is about $= 2p$, the values 1.00651 and 1.01881 for nitrous oxide and ammonia respectively, showing nitrous oxide as nearer to the condition of a perfect gas than ammonia. Thus of the two gases nitrous oxide and ammonia the more nearly perfect gas, nitrous oxide, has a more variable specific heat than the less perfect gas ammonia. But these two gases, as also carbonic acid gas, are too far from perfect gases to justify any inference on that score alone as to specific heats; it is still possible that, if all three gases could have their specific heats

¹ *Pogg. Ann.* 157, pp. 1-42; and *Wied. Ann.* 2, 1877, p. 195.

² *Mém. de l'Acad.* t. xxvi. pp. 251, 252.

determined with sufficient accuracy at such higher temperatures and lower pressures that they conformed in regard to both compressibility and dilatation as well as do hydrogen, nitrogen, and oxygen under normal conditions, the specific heat of each of the three gaseous compounds mentioned would behave similarly. But in fact, as will be seen further on, the nature of the molecule itself affects most powerfully the value of the specific heat; while the specific heat of a gas or vapour increases with rise of temperature, and is independent of the pressure at temperatures such that the gas nearly obeys Boyle's law.

The Ratio of the two Specific Heats.

The ratio (k) of specific heat at constant pressure to that at constant volume is greater than unity; in the case of air and of another gas or mixtures of gases whose dilatation is normal, the *maximum* value of this ratio was calculated by Clausius to be $1\frac{2}{3}$, or 1.6. This number was by A. Naumann¹ supposed to represent the value for gases whose molecules are single atoms and as an example for mercury-vapour.

Relation of k to the Velocity of Sound.

The value of the velocity of sound at any given temperature was shown by Laplace to depend on the ratio k ; so that experiments on a gas from which the velocity of sound can be deduced give the means of determining k . Now values of the velocity of sound in various media have from time to time been found by a number of experimenters, and from these values in the case of gases or vapours approximate values of k have been calculated. Kundt, after determining the velocity of sound by a new method devised by him in 1866² in a number of solid bodies, applied his method, in conjunction with Warburg,³ in 1868 to a comparison of k' for mercury vapour with k for air; a number of determinations were made with different forms of apparatus, and the mean of the values (1.1886) multiplied by the ratio k for air is the ratio k' for mercury vapour. Now Röntgen⁴ found the value 1.405 for air; hence for mercury vapour $k'=1.67$ ⁵ which is almost exactly the same as the number $1\frac{2}{3}$ calculated by Clausius.

Specific Heats of Gases and Vapours at High Temperatures.

The results obtained for specific heats of bodies, simple and compound, in the state of gas or vapour, although of great physical importance, admit of no inference of a general nature as to the relations of specific heats to known properties, physical or chemical, of the chemical elements themselves in the free state or in combination. The specific heats of a few elements and compounds which obey Boyle's and Gay-Lussac's laws very nearly in the gaseous state are approximately, within the limits of temperature 0° to 200° , independent of pressure and temperature, and are such that the heat-capacities of equal volumes are nearly the same for these gases; but with all other gases and vapours this is not true, not even approximately for ammonia or chlorine; and we are far, apparently, from any very important generalisations with regard to specific heats

¹ *Ann. Ch. Pharm.* 142, 1867, p. 267.

² *Pogg. Ann.* 127, p. 497.

³ *Ibid.* 135, pp. 337, 527.

⁵ *Ber.* 8, 1875, pp. 945-948.

of bodies in the gaseous state. And this is the case in spite of very important work in this direction done in recent years, and in which the range of temperature has been extended enormously; yet as the results of these experiments throw light on properties of bodies at high temperatures in the state of gas, and give a new method of investigating specific heats at very high temperatures, they cannot be passed over.

The investigations referred to are those of Mallard and Le Châtelier on the one hand, and on the other those of Berthelot and Vieille; and the method of investigation—which was not directed wholly nor even mainly to the determination of specific heats—was that of exploding explosive gaseous mixtures in a closed spherical or cylindrical metal reservoir, the mixture being exploded alone in some experiments, and in others mixed with varying quantities of one of the two gases of the explosive mixture, or of some other gas; by an explosive mixture being here meant a mixture of two gases in the proportions in which they react to produce the explosion. So far as these investigations are concerned with specific heats of gases, it is evident that these are specific heats of constant volume.

Investigations of Mallard and Le Châtelier.

It is impossible to do justice to the work either of Mallard and Le Châtelier, or of Berthelot and Vieille, in reference to specific heats of gases as deduced from their experiments without an elaborate digest of their work on explosions; it will suffice the purpose of this paper to give a very brief summary of results. The complete work of Mallard and Le Châtelier on the 'Combustion of Gaseous Explosive Mixtures' is published in the 'Annales des Mines,' 1883, 'Mémoires,' t. iv. pp. 274-568, the scope of the communication being (p. 275) the determination for the different gaseous mixtures studied of—

1. The conditions necessary to the production of quick combustion, *i.e.*, the *temperature* of ignition.
2. The *rate* at which inflammation started at a point *propagates itself* in a gaseous mixture, and in general the circumstances which characterise this propagation.
3. The *pressure* which is produced in a close vessel in consequence of the combustion of the gaseous mixture which is enclosed; whence one can deduce the *law of cooling* of hot gases situated in a cold enclosure; the *temperature* produced by the combustion; and finally the nature of the variations which a very high temperature makes in the *specific heats* of gases.

Each of these three parts is the object of a special memoir in this volume.

The Apparatus used.

At first Mallard and Le Châtelier used a modified and enlarged form of eudiometer, such as was used by Bunsen in his experiments¹ but with a Deprez indicator to give the maximum pressure in each experiment; the eudiometer was provided with platinum wires between which an electric spark passing exploded the mixture of gases, and the maximum pressure due to the explosion was recorded. It was soon found, however, that explosions in such an apparatus gave irregular results from which no certain conclusions could be drawn; for explosions in narrow tubes gave

¹ *Pogg. Ann.* t. cxxxi. 1867, p. 161; and *Ann. Chim.* (4), t. xiv. 1868, p. 446.

rise, after a very small fraction of a second from the beginning, in the most explosive mixtures to a very fugitive pressure, due to an effect of the 'explosive wave' discovered by Vieille and Berthelot¹ whereby pressure is added during the propagation of the wave of pressure, so that the pressure of a layer distant from the centre of propagation is momentarily greater than of those nearer, and is therefore greater than the pressure becomes after the very short interval during which it is equalised; the very sensitiveness of the Deprez arrangement and the fact that it recorded just the *maximum* pressure were therefore obstacles against getting a true idea of the state of the gas as a whole during the explosion as to pressure. The explosive wave for oxyhydrogen mixture has the uniform velocity of about 2,810 metres per second; this is called the *specific* velocity of the explosive wave for this gaseous mixture, and is independent of the initial pressure.

The Deprez indicator was therefore discarded in favour of a manometer devised by Bourdon, which indicated the pressures throughout the whole process of explosion and cooling. In place of the eudiometer a cylindrical vessel was used with diameter of its circular base equal to the height of the cylinder, the explosion being made at the centre of the cylinder; the propagation of the explosion in this vessel was free from the irregularities incident to the eudiometer. This wide cylinder in fact was nearer in its shape and in its action to a sphere in which the explosion is started at the centre, this being an arrangement the extreme importance of which was not fully recognised at first; the advantage of the spherical arrangement being that, as the propagation of the explosion takes place uniformly in all directions, the effect would reach all parts of the inner surface of the sphere at the same time, the temperature and pressure would be more rapidly equalised throughout the gaseous mixture, and the cooling would be regular from every portion of the outer surface.

Connected with this manometer was a style for marking on a sheet of paper surrounding a vertical cylinder, which is made to rotate rapidly and uniformly during an experiment, a line representing the rise and fall of pressure throughout the explosion and subsequent cooling.

The whole duration of an explosion is a small fraction of a second in the case of the most explosive mixtures, and generally one second in these experiments is a large interval of time.

Mallard and Le Châtelier. Experiments and Results.

By observation of the rate of cooling, or strictly of the variations of the pressure during the whole period of cooling, after an explosion, through the diminution of pressure as registered by the chronograph for intervals of 0.01 or a smaller fraction of a second, a curve is got giving the relation between pressure and time, intervals of time being registered by the abscissæ, and the pressures by the ordinates. An equation is then found by theory to express the results of direct observation, and the equation is normally that of a straight line, of which the abscissæ and ordinates are known from the conditions and recorded progress of the pressure in each experiment. The form of the equation will be different according as there is or is not condensation, as there is, *e.g.*, when water is one of the products of explosion. Now by these formulæ the rate of cooling is represented by means of a straight line, and this straight line in most cases should cor-

¹ *C. R.* t. xciii. p. 21; t. xciv. pp. 101, 149, 822; t. xcv. pp. 151 and 199; *Ann. de Chim.* (5), 28, 1883, p. 289.

respond with the result obtained from the tracings of the style during the whole period of cooling; this, however, is not always the case, and in the exceptional cases it is found that, if the new curve is plotted out from the numbers given by the experiment, the later portion of the cooling will be represented by a straight line almost exactly for a considerable distance; but the line is found in some cases to be for a portion of its length curved, the curved portion corresponding to very great temperatures and pressures. The interpretation of these cases is that at the highest pressures, and therefore the highest temperatures, there is *dissociation*, and that on cooling the dissociated gases gradually recombine till at the temperature and pressure at which they have entirely combined the line becomes straight through the rest of the cooling. Thus the line deduced from the observed rates of cooling by means of the formula is straight except in cases of dissociation.

A case in point is carbonic acid gas which undergoes dissociation at high temperatures, so that when CO and O are mixed without being dried¹ and the mixture exploded it is calculated that a temperature of 3100° is reached, and that only about $\frac{1}{6}$ of the mixed gases have combined; on cooling the remaining mixture of CO with O gradually combines until at about 1800° there is no dissociation, and from 1800° to the temperature of the room throughout CO_2 is the only gas cooling. H_2O vapour is not dissociated in the conditions of these experiments below 3350° .

From Berthelot's and J. Thomsen's long-continued thermo-chemical researches there are obtainable abundant data for the total heat of combustion of hydrogen, carbon monoxide, cyanogen, methane, for the heat of formation of hydric chloride from its elements, and of the conversion of cyanogen by oxygen into nitrogen and carbon monoxide, and for other reactions between gases which can be brought about by explosion.

In the case of an explosive mixture of hydrogen and oxygen it is found that there is no dissociation at the temperature of combustion 3360° , the pressure corrected for cooling during combustion being 619 cm. of mercury. By adding to the explosive mixture a volume of hydrogen and exploding after this addition, the temperature of explosion, as found from the observed pressure and rate of cooling, is lower the more the mixture is diluted with hydrogen, remaining explosive. Calling now in any case the total heat of combination Q , the temperature (corrected for cooling) T , and c the mean heat-capacity of 18 grams of water-vapour between 0° and T° , we have $Q = cT$; whence c is found to be 16.5 for the high temperature 3360° of this experiment (allowance having been made for water-vapour present before the explosion). Values of c for lower temperatures are found by adding CO_2 to the explosive mixture of hydrogen and oxygen, the explosion giving temperatures at which CO_2 is not appreciably dissociated; from these values of c the next step is to find a formula of the form $c = a + bt$, or with a third term in t^2 , for the heat-capacities of 18 grams of water-vapour for temperatures up to or beyond 3000° .

Returning now to cases in which oxyhydrogen mixture is mixed with hydrogen and this mixture exploded, Q being the heat produced by the explosion, at constant volume, of the hydrogen and oxygen which form 18 parts of water, and m being the mass of hydrogen added, c' the mean heat-capacity of this hydrogen from 0° to the temperature T' produced by the

¹ See Dixon, *Phil. Trans.* 1884, Part II.; and *Chem. News*, 46, pp. 151, 152. 1888.

explosion, we have $Q = (c + mc') T'$, from which now that c is known c' can be found for various temperatures; and hence the specific heat of hydrogen at different temperatures can be deduced. Similarly for the specific heats of oxygen and nitrogen.

Above we have assumed the specific heats of CO_2 known below the temperatures of its dissociation: these are found from the results of exploding CO and O with varying quantities of CO_2 sufficient for the mixture to explode at temperatures below 2000° ; from the results of such experiments, the product being CO_2 alone, a formula can be found to give the specific heats of CO_2 at various temperatures below 2000° .

It should be mentioned in reference to the specific heats of vapour of water that Wüllner¹ deduces, from experiments of his own combined with Regnault's, the number 1.173 as the ratio between the specific heat at 100° and 0° , and that Winckelmann,² from experiments with reference to the coefficients of conduction of heat by gases and vapours, deduced for the same ratio the number 1.172, which agrees closely with Wüllner's.

For the very high temperatures produced in these explosion experiments the observed pressures, which excluded the momentary highest pressure of the explosive wave, often exceed 600 cm. of mercury, but do not exceed 10 atmospheres, and are under 8 mètres; and it may therefore be safely said that, apart from dissociation, the gases raised to these high temperatures at constant volume behave approximately as perfect gases in respect to pressure and temperature, so that for each gas the pressure is nearly proportional to the absolute temperature. The equation $C_p = C_v + 1.98$ therefore holds approximately (p. 28) and gives us an easy method of deducing the specific heats, and also the molecular heat-capacities of the gases at constant pressure.

MM. Mallard and Le Châtelier found that if for any volume of one of the four gases hydrogen, oxygen, nitrogen, carbon monoxide we replace in an explosive mixture of gases an equal volume of another of the four, throughout the whole range of temperatures embraced in their experiments the temperature of combustion remains unaltered; these observations led them to propound in 1882³ the following law: *The molecular heat-capacities of perfect gases which are equal to each other at ordinary temperatures are also equal to each other at about 3000° and perhaps above.*

As the temperature rises the specific heats, not only of gases and vapours in general, but of those called perfect gases also, increase; the latter, it is true, *very much more slowly*, so that the difference between the specific heats of, e.g., water-vapour or CO_2 and of the so-called perfect gases is a great deal more marked at 2000° than at 0° : this is seen in the numbers given below for the molecular heat-capacities at constant volume of

	at 0°	at 2000°
The 'perfect' gases	4.8	6.0
H_2O vapour	5.6	12.2
CO_2	6.3	13.6

HCl was shown to have the same specific heat, or nearly, as the other perfect gases up to 1800° , and to dissociate not much before 2400° , the temperature of explosion of HCl. A similar rapid increase in specific heat with rise of temperature was observed for chlorine as for CO_2 and H_2O . These results were confirmed subsequently by Berthelot and Vieille.

¹ *Wied. Ann.* 4, 1878, p. 7.

² *Pogg. Ann.* 159, 1876, p. 177.

³ *C. R.* 96, 1883.

The authors, by showing that the specific heats of the so-called perfect gases obey the law applicable to all other gases and vapours—that the specific heat increases as the temperature rises—have shown that one supposed distinction between these and the rest does not exist; and draw this distinction between specific heats of gases and Boyle's and Gay-Lussac's volume relations, that whereas the latter are concerned with intermolecular actions mostly and with the motions of the centres of mass of the molecules, *the former are concerned also with the nature of the molecule itself and of the relations of its component parts to each other.*

So far as specific heats are concerned it would seem then that the general results gained by these experiments at very high temperatures were two: that the specific heat in all cases of bodies in the state of gas or vapour increases with the temperature, and that when a gas at high temperatures obeys Boyle's law its specific heat is independent of the pressure; but this is not quite all, for that the laws of specific heats of bodies in the gaseous state are to be looked for in the very molecules themselves is a very important guide for any future investigations.

Papers on portions of the above subject have appeared from time to time in the 'C. R.'; as in 'C. R.' 91, pp. 125–828; 93, pp. 145–148; pp. 1014–1016; pp. 1076–1079; 95, pp. 599, 1352; 97, pp. 102, 157; also in the 'Bull. de la Soc. Chim.'; 'Bull.' 2, 39, pp. 268, 369, 572; 48, p. 122.

In the last-named communication¹ Le Châtelier, noticing that the curves of specific heats of CO_2 and H_2O vapour converge to a point below the absolute zero, infers that probably the specific heats of *all gases* tend to the same limit as the temperature approaches absolute zero. He proposes a formula for the molecular heat-capacities of gases, $C = 6.8 + \alpha T$, at constant pressure, 6.8 being the value for 'perfect' gases, T the absolute temperature, and α a constant for each gas depending on the nature of the molecule of the gas, and being greater the more complex the molecule. Applying this formula to CO_2 and vapour of water, the results for different temperatures agree well with those given by the experiments of Mallard and Le Châtelier. If this result is accepted the problem of specific heats of bodies in the state of gas or vapour reduces itself to that of finding the general relation which connects α with the molecule.

Specific Heats of Gases and Vapours at High Temperatures— Berthelot and Vieille.

The investigations of Berthelot and Vieille on explosions of gaseous mixtures led to similar conclusions to those deduced by Mallard and Le Châtelier as to the specific heats of bodies in the state of gas at very high temperatures.

In the 'C. R.' 94, pp. 101–108 Berthelot and Vieille give an account of the phenomena accompanying the detonation in a long narrow tube of explosive mixtures of hydrogen and oxygen and of carbon monoxide and oxygen, and find the velocities of the *explosive wave* for the two cases, their experiments giving 2,810 metres per second, and 1,089 metres per second for the two explosive mixtures; the theoretical bearing of these results are discussed by Berthelot.² Experiments were made by these

¹ C. S. J. Abs. March 1888, p. 213.

² C. R. 94, 1882, pp. 149–152.

authors with different explosive mixtures, including as combustibles hydrocarbons, cyanogen, and carbon monoxide and nitrous oxide as oxidisers; and the results of mixing the explosive mixture with an inert gas are investigated and the experimental results discussed.¹ A summary of the experimental methods, results, and conclusions drawn from them are given in 'Ann. Chim.' (6), 4, 1885, pp. 13-90.

The apparatus used for the explosions was a *spherical* steel bomb provided with a very exactly fitting piston of known mass and section, by means of which, as it moves under the influence of the pressures developed during the explosion, the motion of a point rigidly connected with it is recorded on a cylinder rotating in a period of about two thousandth parts of a second. The readings were taken at intervals of four ten-thousandths of a second, each interval corresponding in one set of experiments to 5 mm. on a circular section of the cylinder as it rotates round its axis with uniform motion; at intervals of 15 mm. in another set.

Calling lines parallel to the circular section of the cylinder abscissæ and lines parallel to the axis ordinates, values of δy for successive intervals of time δt are easily got, for intervals, say, of time δt corresponding to 5 mm.; and again from this row of values of δy , values of $\delta^2 y$ for equal intervals of time δt are found; thus a series of ratios $\frac{\delta^2 y}{\delta t^2}$ are ob-

tained. The greatest value of these ratios combined with the mass of the piston is the maximum force exerted on the base of the piston during the explosion, whence, from the known mass and section of the piston, the pressure per square cm. is deduced. Thus successive pressures during the explosion, and in particular the maximum pressure, are known.

It is noticeable that Berthelot and Vieille account for the difference between the pressure got by Mallard and Le Châtelier 9.95 atmos. and their own value 10.1 for the explosion of $\text{CO} + \text{O}$ by the statement that their number, 10.1, was got with *dry* gases, while the lower number was the result of exploding in a mixture containing vapour of water; they point also to the fact that Bunsen obtained 10.5 atmos., which agreed with theirs better than with Mallard and Le Châtelier's number. But it is probable that the lower number is more nearly correct, as Dixon has shown² that the results of exploding CO and O partially dried are uncertain, varying according to the amount of the trace of water-vapour present, and that a perfectly dry mixture of the gases cannot be exploded by sparks from an induction-coil.

The following are among the results obtained for temperatures up to 3000° and even getting on to 4000° (air-thermometer):—

The specific heats of gases are independent of the density or of the volume of unit mass at these high temperatures, as is the case near 0° . The apparent specific heat (of a gas or a gaseous mixture) increases as the amount of heat absorbed increases. These conclusions (p. 58) are arrived at independently of any hypothesis about laws of gases and their physical constitution, *i.e.*, independent of Avogadro's hypothesis and of any views as to the molecular constitution, and without assuming the applicability of Boyle's and Gay-Lussac's laws (p. 51).

Mallard and Le Châtelier did not give results for the highest pressures (and temperatures) given by the explosions; but for temperatures up to

¹ *C. R.* 94, p. 822; 95, pp. 151, 199.

² *Phil. Trans.* 1884.

about 2800° for the specific heats of hydrogen, oxygen, nitrogen (the so-called 'perfect gases'), as also of carbon monoxide and hydric chloride, they found results agreeing with the formula for C_v , the specific heat at constant volume

$$C_v = 4.8 + .0006t.$$

Berthelot and Vieille found by experiments for greater pressures and higher temperatures values for C_v greater than were given by this formula; and it is certain that the above formula cannot legitimately be used for temperatures much higher than those on observations at which the formula is founded; on the other hand, it is doubtful whether the results obtained from observations concerned only with the very highest pressures are so accurate as the others. However this may be, Berthelot and Vieille find that the mean specific heats of equal volumes of hydrogen, oxygen, nitrogen, and carbon monoxide at constant volume is doubled in passing from 0° to 4500° ; and they give the formula $C_v = 6.7 + .0016(t - 2800)$ for temperatures above 2800° . Except in respect of these very high temperatures, the results agree for the gases named remarkably well with those of Mallard and Le Châtelier.

Gases such as chlorine, nitrous oxide, carbon dioxide, which have specific heats between 0° and 200° greater than those of the gases mentioned, and which, according to Regnault's results and those of E. Wiedemann, have nearly equal specific heats at these lower temperatures, have nearly equal specific heats at about 1800° .

For vapour of water the molecular heat-capacity was found to be 18.12 at 3240° . Mallard and Le Châtelier had found 16.6 at 3350° and that there was no dissociation at this temperature: these results are in fair accordance with those of Berthelot and Vieille.

These authors go on to discuss the absorption of heat in the form of specific heat and in dissociation; attributing the former to actions on the molecules themselves either in increasing the kinetic energy of rotation and vibration of the molecules or of their component parts, or to a disgregation of the molecules without dissociation; as in the cases of CO_2 and N_2O , in which cases heat is absorbed up to 200° , as shown by Regnault's results as to the specific heat of these gases and the increase of specific heat with rise of temperature.

This absorption of heat during the disgregation of molecules, &c., as shown by the rise of specific heat with rise of temperature has an important bearing on the heat of combustion at different temperatures, as, e.g., in the cases of CO and H_2 to form CO_2 and H_2O . In the case of the formation of HCl from 1 gram of hydrogen at constant pressure, although this gives 22,000 thermal units at 0° , yet at 2000° the heat evolved is about 26,000, the difference being due (apart from dissociation) to the very great increase in the specific heat of chlorine between 0° and 2000° ; whereas 1 gram of hydrogen, in combining with oxygen to form water, evolves at 0° 29,000 units, and at 2000° (in consequence of the great rise in the specific heat of H_2O vapour from 0° to 2000°) 25,300; hence the heat of combination of H_2Cl is greater than that of $\frac{1}{2}(\text{H}_2, \text{O})$ at 2000° , although less at 0° , at constant volume. In the explosions of hydrogen and oxygen, and of hydrogen and chlorine, in closed vessels there appears to be little or no dissociation of HCl or of H_2O at 2000° .

At p. 84 of this volume of the 'Ann. Chim.' Berthelot questions the validity of Avogadro's hypothesis and its applicability in particular

to chlorine and iodine, and prefers interpreting the diminishing density of both at very high temperatures by admitting these to be among numerous exceptions to Boyle's and Gay-Lussac's laws; 'there exists,' he says, p. 83, 'no valid reason for preferring, in the definition of temperatures, the indications of an air-thermometer to those of a chlorine-thermometer.' Now Sir W. Thomson¹ had shown that Carnot's function affords a foundation for a system of thermometry not dependent on special properties of some individual substance, but derivable from the properties of any substance whatever; and in conjunction with Joule published a series of investigations 'On the Thermal Effects of Fluids in Motion'² in which the authors arrived at a means of estimating temperatures on an absolute scale.

The definition given³ shows the principle on which the absolute system of thermometry is founded, by which temperatures are measured on 'the thermodynamic scale'; 'if any substance whatever, subjected to a perfectly reversible cycle of operations, takes in heat only in a locality kept at a uniform temperature, and emits heat only in another locality kept at a uniform temperature, the temperatures of these localities are proportional to the quantities of heat taken in or emitted at them in a complete cycle of the operations.'

From the experiments of Joule and Thomson, in which gases, *e.g.*, air (hydrogen; and carbon dioxide) was made to pass through a porous plug at various pressures, the change of temperature being observed, results were obtained by means of which a formula was deduced, giving the absolute temperature in terms of the temperature by the air-thermometer, and a table of corrections for temperatures from 0° C. up to 300° C. by which these air-thermometer temperatures might be converted into temperatures on the thermodynamic scale; the correction not exceeding, within this range of temperatures, half a degree on either scale whether for air at constant pressure or for air at constant volume.

Relation of Volume to Temperature—Solids and Liquids.

The rates of expansion of bodies in the solid and liquid states are very much smaller in general than in the gaseous state; this rule does not always hold, however, for liquids under the critical point when subjected to great pressures, as shown first by Thilorier for CO₂, the expansion of which in the liquid state under the conditions specified exceeds that of gaseous CO₂.

Solids.

For solids a very large number of results, sufficiently accurate for the purpose at least of drawing an inference of a general kind, were obtained by a number of experimenters about the end of last century and the beginning of this, showing that the *coefficients* of linear expansion of a large number of metals and alloys, and of glass, between 0° and 100° lie in general between 10^{-5} and 3×10^{-5} ; to these have been added results got by Dulong, Regnault, Kopp, for metals and other elements, for varieties of glass, and for a number of minerals for this temperature-range, and for higher temperatures in some cases; by Playfair and Joule for a number of crystalline compounds; ⁴ by Pfaff,⁵ and by others. *

¹ *Camb. Phil. Soc. Proc.* June 5, 1848; and *Phil. Mag.* Oct. 1848.

² *Phil. Trans.* 1853, 1854.

³ *Ibid.* 1854, p. 351.

⁴ *C. S. J.* 1, 1849, p. 121.

⁵ *Jahresb.* 1858, p. 7.

The general result of these data is that solids in general expand very slowly indeed with rise of temperature, at least between 0° and 100° , but as the temperature-limit is increased so as to include higher and higher temperatures the rate of expansion in general increases; if the coefficient of linear expansion remained constant a unit length at 0° would become $1 + at$, where t is the coefficient of linear expansion, the cubical expansion being approximately $1 + 3at$, in which $3a$ is the coefficient of cubical expansion; or if we determine the coefficient of cubical expansion α that of linear expansion is $\frac{\alpha}{3}$. But in general it is necessary to add a term in t^2 to express with sufficient accuracy the results of experiments.

Although many most accurate determinations have been made in recent times on the expansion of solids the results are not connected with any general laws, as in the case of the expansion of gases with rise of temperature.

Liquids.

Mercury.—The absolute expansion of mercury was determined by Dulong and Petit and their results given on p. 136, 'Ann. Chim.' (2), 7, 1818. Regnault, using Dulong and Petit's general method with improvements, made an extensive series of determinations of volumes at 0° and 350° , and for every interval of 10° between these limits, with the coefficient of expansion at each temperature and the mean coefficient between that temperature and 0° C.¹ At temp. 100° the true coefficient is given as 0.00018305 by misprint for .00018405.²

By means of the absolute expansion of mercury it is easy to find the expansion of a thermometer-tube or other similar glass vessels in which the expansions of liquids are observed, so that from the apparent expansion of the liquid in the *dilatometer*, as such an instrument is called, the true expansion may be determined. This is of fundamental importance for the determination of the expansions of liquids. For results obtained by Bosscha and Wüllner see 'Jahresb. f. Chem.' 1874, p. 70.

Water.—Feltz³ gives an account of experiments by Rossetti (professor at the University of Padua) on the maximum density and the dilatation of distilled water; for the temperature of maximum density Rossetti finds 4.07° , agreeing very closely with H. Kopp's value 4.08° ⁴ and differing from 4.00° given by Despretz,⁵ and from 3.92° given by Pierre.⁶ The above-named and other experimenters gave tables for the volumes and densities of water at temperatures up to 100° C. and below 0° ; Sorby⁷ and Mendelejeff⁸ gave results for water above 100° ; and Hirn⁹ for a number of other liquids, chiefly organic, up to and above their ordinary boiling-points, and in the case of water up to 200° . In the case of water the rate of expansion is more rapid the higher the temperature above (about) 4° ; and below this, in the unstable condition of water remaining liquid below its ordinary freezing-point it expands as temperature sinks; in other words, at 4° water has its maximum density, the densities diminishing from 4° to -10° , and from 4° to 200° . as to the relation of volume to temperature for liquids generally see footnote.¹

The more or less successful attempts of Kopp and of Schröder to find relations connecting the volumes of liquid compounds at their boiling-points, with volumes of their component atoms, were based on the idea that liquids should be comparable among one another at their boiling-points (or at points equidistant from these).

Volume and Temperature. Liquids—Recent Investigations.

Ramsay² made a number of determinations by a new and ingenious method in which the liquid was heated to the temperature of its boiling-point in a small glass vessel from which, by the expansion of the liquid, drops of it overflowed, as the temperature rose, into a larger vessel surrounding it. This latter vessel had a small portion of the liquid to be examined, which was kept boiling vigorously by a flame under it, so that the inner vessel was kept constantly surrounded by the vapour at the boiling-point of its own liquid. By this arrangement the density of a volatile liquid at its boiling-point is determined.

Thorpe³ made a most extensive series of determinations of a large number of liquids for temperatures at intervals between 0° and over 100° (air-thermometer), every precaution being taken to secure against sources of error, the results being expressed by equations of the form $V = 1 + at + bt^2 + ct^3$, where V is the volume at temperature t .

To find a Simple Relation between V and t for Liquids.

The question arises whether—out of all the abundant and accurate material at hand as the result of experiments made on large numbers of liquids at such a range of temperature for each liquid that its expansion may be expressed generally with great accuracy in terms of the temperature by formulæ like that just written—it is not possible to find some simple approximate expression for the expansion which could be applied to each liquid by giving to a constant in the expression a number corresponding to each. In respect of the expansion of gases such an expression is supplied by Gay-Lussac's law, which is an ideal law to which bodies conform in the gaseous state, and is such that bodies in the ideal gaseous state expand equally for equal increments of temperature. In respect of liquids, as will be seen at once by inspecting tables of volumes of bodies in this state, the expansion is very obviously different for different liquids. Any expression, therefore, for their expansion must involve some constant which is special to each.

Bosscha⁴ has proposed $V_t = V_0 \times e^{at}$ in which a is a constant characterising each liquid. Avenarius⁵ proposed another formula; and others before these dates have made attempts to find simple formulæ. In

Mendelejeff's Relation between V and t for Liquids.

Mendelejeff¹ proposes the formula $V = 1/1 - kt$, similar to Gay-Lussac's formula for gases, but in which k is a specific constant for each liquid; and substantiates this as an approximate formula by applying it to the volumes given by Thorpe for liquids at various temperatures, 10° , 30° , 60° , and in some cases 150° . Arranging 47 liquids studied by Thorpe in order of their rates of expansion with rise of temperature, from the least to the most expansible, an inspection of the figures is sufficient to suggest at once the idea that all expand in a similar manner, and that the difference between their expansions is one of scale only. This is shown by Mendelejeff by taking the expansion for mercury as calculated by him from Regnault's results in the form $V = 1 + 10^{-3} \cdot 1801T + 10^{-7} \cdot 2T^2$, in which T is any temperature of the mercury. Comparing the expansion of mercury with that of PBr_3 , one of the least expansible of the liquids given in the table, and with nitric peroxide N_2O_4 , the most rapidly expanding liquid of those given, Mendelejeff shows that 46.8° , 93.7° , 140.9° , 189.1° are temperatures T at which the volumes of the mercury (vol. at $0^\circ = 1$) are the same as are the volumes of PBr_3 at temperatures t such that T/t is 4.68, 4.68, 4.69, 4.72. So for comparison of the volumes of mercury and nitrogen peroxide at temperatures T and t respectively, he finds for mercury at temperatures 43.6° , 86.5° , 129.7° , 174.6° the same volumes as nitrogen peroxide has at temperatures 5° , 10° , 15° , 20° respectively, so that in this case T/t has the values 8.72, 8.65, 8.65, 8.70, showing that phosphorus tribromide expands 4.7 times more strongly than mercury, and nitrogen peroxide 8.7 times more strongly than mercury, but in qualitative respect the expansion of these as well as other liquids is on a uniform plan.

As the density of a mass is inversely as its volume, if we take the density of a liquid at 0° as 1, the density $D = 1 - kt$ at the temperature t ; hence $dD/dt = -k$ (or if density is D_0 at 0° , $D = D_0(1 - kt)$, and $dD/dt = -kD_0$). This result is remarkably confirmed by some specific gravity determinations, by Miss E. K. Gutkowska in Mendelejeff's laboratory in 1881, of some American kerosene (petroleum). At 0° , 16° , 32° , 48° the specific gravities found were .8056, .7940, .7824, .7708, whence an equal difference .0116 for equal temperature-intervals; here $\frac{dD}{dt} = \frac{.0116}{16} = - .000725$. Similar results were obtained for Baku petroleum.²

Mendelejeff remarks that he found in 1860³ that the coefficient of change of density of liquids varied more simply than the coefficient of change of volume; and that this, combined with his investigations from 1880 to 1883 (*loc. cit.*) of the products of distillation of Baku petroleum in which he was obliged to find the change of density with changing temperature, induced him to consider all liquids in reference to changes of density rather than volume in the first place, and that he thus arrived at the law of expansion $V = 1/1 - kt$.

¹ *C. S. J.* 1884, p. 126.

² *Russ. Phys. Chem. Soc. Journ.* 1883, p. 189.

³ *L. Ann.* 114, 165.

The author finds that liquids near their boiling-point show some deviation in their rates of expansion from those calculated from the above formula, in the sense that the observed expansion is greater than that calculated; e.g., the volume of PBr_3 , B.P. 173° , is found at 160° to be 1.1562; the calculated value ($k = .000841$) is 1.1555; on the other hand in one case, that of a paraffin melting at 38° , Beilby has¹ shown that the change in its specific gravity with temperature is from 38° to 60° quite constant; $\frac{dD}{dt} = -.000727$; the deviations of volatile liquids from perfect accordance with the law expressed by the formula are nearly always small, but near the boiling-point quite appreciable; and for different liquids the deviations are of different sign; if we consider Mendelejeff's equation as expressing the ideal form of expansion for liquids by analogy with Gay-Lussac's expression for expansion of gases, then the deviations from the ideal form will be greater, the less the density of the liquid, the greater the cohesion (the value a^2), the less the molecular weight, i.e., the less the vapour-density. Water has a small molecular weight and very great cohesion, the molecular weight being the smallest for all common liquids; these facts, taken in conjunction with the small difference between the temperatures at which liquid water changes its state of aggregation to the solid and gaseous respectively, account for the anomalies in the expansion of water; for which, in fact, the equation does not hold, the values of k found within different temperature-ranges being quite different. No other liquid shows so rapid a rate of expansion from 4° .

On p. 132, in a footnote, Mendelejeff refers to a paper by him in which he has shown a dependence of coefficient of expansion of gases on the molecular weight; this coefficient *increases* with increasing molecular weight. He draws special attention to the case of chlorine, which, therefore, has a large coefficient of expansion: this fact, he says, should be taken into account in regard to the alleged dissociation of the chlorine molecule.

Thorpe and Rücker on the Relation of k to Critical Temperature.

In the paper immediately following Mendelejeff's (*loc. cit.* p. 135), Thorpe and Rücker discuss the formula given by Mendelejeff in connection with Van der Waals' theories. The result of this paper is to show a simple relation connecting k , Mendelejeff's *determinator* of expansion, with the critical temperature of the liquid.

In the Leipzig edition (1881) of Van der Waals' dissertation on the continuity of the gaseous and liquid conditions, on p. 128, he states two general relations, which show that temperatures and pressures are *corresponding* temperatures and pressures for two different bodies when they are such that the ratio of the absolute temperature in the case of one body to the absolute critical temperature of that body is the same as this ratio for the other body; for when the pressure, volume of liquid, volume of saturated vapour for the two bodies at these two temperatures are compared, the ratios of these pressures and volumes are found also to be in the same ratio to their values at the critical temperature—the same, that is, for both bodies. *Corresponding* conditions for two

¹ C. S. J. 1883, *Trans.* 338.

² C. R. Feb. 14, 1876.

bodies—not solid—are therefore conditions under which, in the above sense, temperature, pressure, and volume correspond; the boiling-points at any pressure are not, therefore, points at which bodies are to be expected to correspond in physical properties, and the principle of Kopp's method and that of others for comparing bodies as to molecular volumes or molecular heats is in this particular not strictly correct.

On page 152 of Van der Waals' 'Continuity, &c.,' the following conclusion is stated: 'The coefficients of expansion of individual bodies under corresponding conditions (of temperature, &c.) are inversely proportional to the absolute critical temperatures of the bodies'; in which, from the context, it is seen that by the coefficient of expansion of volume v at absolute temperature T is meant $\frac{1}{v} \frac{dv}{dT}$, in which $\frac{dv}{dT}$ is the *partial* differential coefficient, being rate of variation at temperature T with the temperature only and without alteration of pressure.

Hence for any pair of corresponding temperatures the values of $\frac{1}{v} \frac{dv}{dT}$ are to each other inversely as the absolute critical temperatures of the two bodies: and therefore if T_1 is this temperature for one of the bodies, $\frac{1}{v} \frac{dv}{dT} \times T_1 = C$, a quantity which is the same for each body. Now Mendelejeff's formula may be written $1/v = 1 - k(T - 273)$;

whence

$$\frac{1}{v^2} \frac{dv}{dT} = k;$$

and

$$\frac{1}{v} \frac{dv}{dT} = k / (1 - k \cdot T - 273);$$

therefore

$$\frac{1}{v} \times \frac{dv}{dT} \times T_1 = k T_1 / (1 - k \cdot T - 273);$$

therefore

$$1 - k(T - 273) = k T_1 / C;$$

and

$$\frac{1}{C} = (1 + 273k) / k T_1 - T / T_1.$$

But C must be independent of the individual body, and dependent only on the ratio T/T_1 ; and k is dependent *not* on T but on the body and therefore on T_1 . These conditions are satisfied if

$$1 + 273k = a k T_1 \quad . \quad . \quad . \quad . \quad . \quad (a)$$

so that $\frac{1}{C} = a - T/T_1$, a being an absolute numerical constant. We thus

have an equation connecting a , k , and T_1 which, when the value of a is known, will give Mendelejeff's k in terms of the absolute critical temperature of the body. This equation (a) may be put in this form:—

$$1/k = a T_1 - 273;$$

from which

$$1/k - (T - 273) = a T_1 - T;$$

so that

$$1/v = k(1/k - t) = k(a T_1 - T).$$

Hence the density of a given liquid is directly proportional to the result of subtracting the absolute temperature from a times the absolute critical temperature of the body.

To determine the value of a we have then to find a number of bodies

which, in the liquid state, conform to Mendelejeff's law with sufficient accuracy, and of which the critical temperatures also are known; if the values of a so found are nearly equal we have a strong confirmation of the relation between k , a , and T_1 expressed in equation (α).

The relation between the volumes at t° and 0° (ordinary scale, air-thermometer) is that

$$\frac{v_t}{v_0} = \frac{aT_1 - 273}{aT_1 - T};$$

whence, if $v_0=1$,

$$a = \frac{Tv_t - 273}{T_1(v_t - 1)},$$

the equation by which the values of a may be obtained.

The authors give a number of tables of values of t or $(T-273)$ and v_t for different liquids, for which in each table the critical temperatures have been determined by some one observer, together with the value of a in each case. The table annexed—Table 1, p. 138—in which the critical temperatures have been determined for all the bodies by Sajotschewsky,¹ is a good illustration:—

Substance	t	v_t	T_1	a
Ethyl chloride	10	1.0160 P.	455.6	1.993
Ether	30	1.0483 K.	463.0	1.996
Benzene	80	1.1064 K.	553.6	1.996
Ethyl formate	50	1.0735 K.	503.0	1.995
Ethyl acetate	70	1.1040 K.	512.8	1.981
Methyl acetate	50	1.0733 K.	502.8	1.999
Chloroform	60	1.0818 T.	533.0	2.001

The letters P, K, T indicate that the expansions were determined by Pierre, Kopp, Thorpe. The mean value of a is found to be 1.995, which nearly agrees with each individual value.

Other tables are given, in which critical temperatures are made use of which had been found by Ramsay² and Pawlewski.³ The result of all the determinations is to show that a differs from 2 by a very small fraction. For a perfect liquid (*i.e.*, where k is constant) we have, at constant pressure—

$$\frac{v_t}{v_0} = \frac{2T_1 - 273}{2T_1 - T}; \text{ for perfect gases } \frac{v_t}{v_0} = \frac{T}{273}.$$

From equation (α) we have now—

$$1/k = 2T_1 - 273 (\beta)$$

a formula by means of which, in the case of a volatilisable liquid generally, the critical temperature can be calculated from observations on its 'expansion' as a liquid.

On page 144 is given a table of the observed absolute critical temperatures of the bodies in the table cited, and by side of these the calculated critical temperatures. The correspondence is so close that it is worth while to reproduce the table here.

¹ *Wied. Beibl.* 1879, p. 741. ² *Proc. Roy. Soc.* 31, 194.
³ *Ber.* 15, 1882, p. 2450; 16, p. 2633.

Absolute Critical Temperatures.

	Observed	Calculated	Difference
Ethyl chloride	455.6	455.2	— 0.4
Ethyl oxide	463.0	463.8	+ 0.8
Benzene	553.6	553.8	+ 0.2
Ethyl formate	503.0	502.9	— 0.1
Ethyl acetate	512.8	509.3	— 3.5
Methyl acetate	502.8	503.9	+ 1.1
Chloroform	553.0	534.8	+ 1.8

It is noticeable, too, that the errors fall in both directions.

Objections by MM. Bartoli and Stracciati.

In the course of a study of the physical properties of American petroleum (from Pennsylvania) MM. Bartoli and Stracciati¹ criticise the propositions of Mendelejeff on the volumes of liquids and their expansion by heat, and the deductions of Thorpe and Rücker from Van der Waals' and Mendelejeff's conclusions.

Mendelejeff's 'very interesting memoir' is resolved by these authors into three propositions:—

(A) Any two liquids which dilate equally between (say) 0° and 10° will dilate equally between 0° and t° ; and if the dilatation of one liquid is greater or less than the other liquid between 0° and 10°, it will also be greater or less between 0° and t° .

(B) Let $V_0, V_1, V_2, \dots, V_n$ be the volumes of a liquid at temperature 0°, t_1, t_2, \dots, t_n ; then, if another liquid has the same volumes at temperatures 0°, t'_1, t'_2, \dots, t'_n , we shall have—

$$\frac{t'_1}{t_1} = \frac{t'_2}{t_2} = \frac{t'_3}{t_3} = \dots = \frac{t'_n}{t_n}.$$

(C) The volume V_t of a liquid at temperature t is expressed (in terms of the volume at 0° as unit) by the equation, $V_t = 1/(1 - kt)$.

They proceed to say that proposition (A) can only be taken as an approximation, and that 'it is easy to see' that it is deduced from the formula of Van der Waals.

Now Mendelejeff says,² 'Just as for gases the expression $V = 1 + kt$ applies only to a first approximation, or to a so-called ideal gas, so does the expression $V = (1 - kt)^{-1}$ apply for liquids only to a first approximation, namely, to 'ideal liquids,' giving in a foot-note his idea of the characteristics of an ideal liquid. Mendelejeff has not claimed more for his formula and his general conclusions than that they are approximate.

Again, 'it is easy to see' that Mendelejeff's result, as embodied in A, is deduced from the formula of Van der Waals may mean that *it is not easy to show*; if these authors had shown this they would have given a theoretical confirmation of a result of Mendelejeff's experience.

Again, they object that if proposition (B) is true, then in the formula which expresses accurate determinations of expansions of many liquids, viz., $V_t = 1 + at + bt^2 + ct^3 + dt^4$ we should have $a = b/a = c/b = d/c = k$; relations which are not verified: this would be a fatal objection if Mendelejeff

¹ *Ann. Chem. Ph.* (6), 7, 1886 p. 384.

² *C. S. J. Trans.* 45, 1884, p. 131.

maintained that his results were rigidly accurate; but as they are only approximate the objection falls to the ground.

Again, they give a table for the dilatations of water and other liquids which Hirn had studied at a pressure of 11·5 metres of mercury; and deduce from these tables, by means of Mendelejeff's formula, the value of k for water, from 100° to 200° ; for alcohol, from 50° to 200° ; for ether, from $21\cdot55^{\circ}$ to $133\cdot66^{\circ}$; and for (essence of) terebenthene from 40° to 160° .

The value of k for each substance in these determinations they find not to be constant but to vary with t , increasing as t rises; now the first example chosen is that of water, which even below 100° Mendelejeff finds to be a quite remarkable exception in being far removed from an ideal liquid; and with regard to the other examples (to which are added in this paper of Bartoli and Stracciati, ammonia, nitrous oxide, carbon dioxide, and ethyl chloride), it may be remarked that in Mendelejeff's paper, p. 131, there is this foot-note:—'A subject for further experimental investigation would be the solution of the question, in what manner and how much the expansion of volatile liquids is changed at different pressures. I should like to submit this theoretically important question to an experimental solution.'

The Continuity of the Gaseous and Liquid States.

In nature we find no substance which is an ideal gas or an ideal liquid; however nearly a body may conform to either of these ideal states within certain limits there are always deviations from such conformity outside those limits; so that volatilisable liquids, which in one direction tend to obey Mendelejeff's law within certain limits of temperature, in the other direction will, in general, under suitable conditions, tend to conform with Gay-Lussac's law. There is, however, in all cases a more or less considerable range of intermediate conditions in which the expansion of the body is not even in approximate conformity with either law.

Andrews¹ showed by experiments on various bodies that, when a condensible body is in the state of vapour, there exists a temperature—the critical temperature—at and above which no amount of pressure could make any appearance of discontinuity in the body acted on: no meniscus could be observed indicative of the separation of the body—*e.g.*, CO_2 —into two distinct portions of different densities; above the critical temperature there is, as shown by graphic representation of the experimental results, a *continuous* curve for each temperature.² Below the critical temperature a sufficient pressure produces a meniscus, indicating a separation of the body into a heavier and lighter portion; and generally, at temperatures below the critical, the diagram representing the variation of volume with pressure showed a portion of the line as straight during the compression so long as the less dense upper portion was visible; after this the curve shows a rapid increase of pressure with given decrease of volume. The whole line of pressure-volume consists, roughly speaking, at these lower temperatures of two curves joined by a straight line. Above the critical temperature there is perfect continuity; below it, discontinuity; above, the relation between p and v (t constant) could conceivably be expressed by an equation representing the continuous curve;

¹ *Phil. Trans.* ii. 1869, p. 575.; and 1876, p. 421.

² *Ibid.* 1869, p. 575.

and a single equation might give a relation between p , v , and t , which would apply to all pressures and volumes, and to temperatures above the critical point. Yet from the discontinuity at lower temperatures this equation would hardly seem applicable throughout.

In 1871¹ James Thomson suggested that the isothermal curves are not really but only apparently discontinuous, and that their true form is such that in place of the straight part there is a curved part continuous with the rest, and situated partly on one side and partly on the other of the straight part.²

The transition from the gaseous to the liquid state, in this view of James Thomson, is gradual, regular, and continuous for each temperature; and the idea of finding a mathematical relation between p , v , and t for all temperatures may be realised. Such perfectly general equations have been given by Van der Waals, Clausius, and others; but however approximately these formulæ represent certain sets of experiments, none seem to have been proved to have the generality required.

Less general relations we have, as Boyle's, Gay-Lussac's, and Mendelejeff's laws; a law stated by Amagat as applicable to fluids under great pressure: $p(v-a)=\text{const.}$ [*Ann. Chim. Ph.* {5}, 22, 1881, p. 395]; and another by Amagat for high temperatures or low pressures: $p=c(t-t_0)$ [*Ann. Chim. Ph.* {5}, 28, 1883, pp. 505, 506], and [*C. R.* 94, 1882, p. 847].

General Equations for p , v , and T .

The general equations of Van der Waals, Clausius, and others, though not yielding results fully in accordance with all the experiments for bodies in the state of liquid or of gas or vapour by Amagat and others, give so close an agreement through large ranges in cases to which they have been applied that each of them must be looked upon as a tolerably close approximation; the most important of these equations are:

$$pv = RT - \frac{c}{T}; \text{ Rankine.}^3$$

$$(p+r)(v-\psi) = RT; \text{ Hirn.}^4$$

$$pv = RT \left(1 - \frac{B_t}{v}\right); \text{ Recknagel.}^5$$

$$\left(p + \frac{a}{v^2}\right)(v-b) = RT;$$

$$\text{or, } p = R \frac{T}{v-b} - \frac{a}{v^2}; \text{ Van der Waals.}^6$$

$$p = R \frac{T}{v-a} - \frac{c}{T(v+\beta)^2}; \text{ Clausius.}^7$$

$$\frac{p}{RT} = \frac{1}{v-a} - \frac{AT^n - B}{(v+\beta)^2}; \text{ Clausius.}^8$$

These equations are to be found in the articles by Clausius, in 'Wied. Ann.' referred to; and in 'Ann. Chim.' 5, 30, 1883, pp. 358 and 433, in which Clausius' articles are translated.

Another equation is given by Sarrau,¹ as a modification of Clausius':

$$p = \frac{RT}{v-a} - \frac{Ke^{-\tau}}{(v+\beta)^2}.$$

Ramsay and Young's Isochoric Lines.

In the 'Philosophical Magazine' for May and August 1887 is published Part VI. of a series of papers by Ramsay and Young on Evaporation and Dissociation. In this part, from very copious data extending over large ranges of pressure, temperature, and volume, a relation is deduced from the isotherms for ether, carbon-dioxide, methyl alcohol, and ethyl alcohol, from which the following conclusion is drawn:²—'The relation between the pressures and temperatures of a liquid or gas at constant volume is expressed by the equation $p=bT-a$, where p is the pressure in millimetres, T the absolute temperature, and a and b are constants. The values of these constants depend on the nature of the substance and on the volume. It follows from this that if a diagram be constructed to express the relations of pressure, temperature, and volume of liquids and gases, where pressure and temperature form the ordinates and abscissæ, the lines of equal volume are straight.' These lines are called isochors.

From very numerous data obtained by themselves for ether, and published in 'Phil. Trans.' 1886, p. 10, the authors found series of values of p and t° , from which it was seen that for each volume v of a gram of the substance the lines passing through points, in which p and t were taken as ordinates and abscissæ, were, at least approximately, straight. The volumes in the case of ether ranged from 1.9 cc. to 300 cc.; the pressures from 860 mm. to 52,700 mm.; and the temperatures from 50° to 280° C. For each isochor the value of $\frac{dp}{dt}$ (or b) was

found by finding the whole difference of pressure through the largest range of temperature; and the value of a by taking the mean of the values for different points on each isochor. The isochor constructed by drawing the line $p=bT-a$ was found to agree wonderfully well throughout with the points found by experiment; the equation for each being verified by deducing from the series of isochors thus found the isotherms; these calculated isothermal lines were found to give results agreeing very closely indeed with actual observation.

Clausius³ had drawn attention to the fact that the line of observed vapour-pressures must cut James Thomson's curve in half, so that the volume above the line is equal to that below it. Now the equation $p=bT-a$ represents the whole series of isochors for ether by putting for b and a their values for each volume; and the calculated isothermal lines pass close to the observed points on them; but for values of v corresponding to the sinuous part of each isothermal, the value of p can be calculated from the equation; this part of the curve can be traced by means of the equation, assuming that the relation $p=bT-a$ applies to the part of the curve on which we have no observations as well as to the

¹ C. R. ci. 1885, p. 1145.

² Phil. Mag. May 1887, p. 436.

³ Wied. Ann. 9, 1879, p. 127; Ann. Chim. 5, 30, 1883, p. 381.

remainder. Ramsay and Young devised a method for constructing the horizontal line (line of equal pressures on Andrews' diagram corresponding to the vapour-pressure for any temperature), and obtained these lines for the various isothermal lines so accurately dividing the volumes into equal parts that it was found that the vapour-pressures thus indicated agreed with those of experiment within 1 per cent. This is a remarkable confirmation of the accuracy with which $p=bT-a$ represents lines of equal volume.

Similar results were obtained for CO_2 , and for methyl alcohol and ethyl alcohol; and the equation $p=bT-a$ was confirmed as a remarkably accurate representation of the lines of equal volume for these bodies in the gas-liquid state.

For acetic acid and for nitric peroxide the isochoric lines were not straight, but were curved in such a way that points on them for high temperatures were on nearly straight lines, which would be isochors for the formulæ $\text{C}_2\text{H}_4\text{O}_2$ and NO_2 , supposing that compounds with these formulæ in the gas-liquid state behaved as alcohol and ether do; it is noticeable that in the gaseous state acetic acid and nitric peroxide do not attain constant vapour-densities till they have been heated considerably above their boiling-points. It must be observed, however, that this is a matter of degree; and so far as acetic acid is concerned, there is as yet hardly sufficient reason for supposing that acetic acid forms a true polymer. The case of nitric peroxide is, perhaps, a case of polymerism in which we have two distinct chemical substances, NO_2 and N_2O_4 : there are, in fact, distinct physical differences between nitric peroxide at a low and a high temperature.

On the Nature of Liquids.

In a paper on this subject¹ Ramsay and Young bring forward a number of considerations from researches of their own,² among which is a series of determinations of densities of the *saturated* vapours of alcohol and acetic acid; in both these cases the vapour-density, at high temperatures, becomes abnormally great: thus, for alcohol at temperature about 250° the pressure is 32,000 mms., and the vapour-density of the saturated vapour 45, the normal being 24 from the formula; for acetic acid at 250° and 15,000 mms. the saturated vapour-density is 55. But there is this difference between the two cases: the vapour-density at saturation diminishes continually with alcohol till it becomes normal, *i.e.*, 24 at about 20° —similar results to these were got for ether. The case of acetic acid is quite different; for, although at temperatures above 150° the saturated vapour-density continually increases with rise of temperature, and this vapour-density sinks as temperature falls to 150° , yet, as the temperature falls below 150° , the vapour-density begins to increase again, till at 20° it is the same as at about 270° ; nor does it become normal, although at 20° the pressure is only a few millimetres, and the vapour-density 59 nearly corresponds to 60 for $(\text{C}_2\text{H}_4\text{O}_2)_2$; but the nature of the curve of vapour-densities of acetic acid at saturation does not suggest a limit at this point.

Ramsay and Young argue thus with respect to acetic acid: High temperatures are favourable to chemical decomposition, or dissociation of complex molecules; and we therefore have no reason for assigning to

¹ *Phil. Mag.* Feb. 1887.

² *Phil. Trans.* 1886, Part I.

acetic acid on the score of its saturation vapour-densities at the higher temperatures any essentially different molecular arrangement than we do to alcohol and ether. Now, for these latter bodies, the vapour-densities at saturation are at *low* temperatures normal, *i.e.*, normal under conditions of temperature more favourable to complex molecules: Seeing that complex molecules of alcohol are not formed at low temperatures, *à fortiori* they are not at the higher temperatures; there is no reason, seeing that at the higher temperatures alcohol and acetic acid behave similarly, for supposing that acetic acid has other than a normal molecular constitution at higher temperatures: But there remains the peculiarity of acetic acid, that its saturation vapour-density below 150° increases continually. The pressure being relieved, we should expect, as in the case of alcohol, that as the pressure diminishes with the temperature the vapour-density would get smaller till it is normal. There must, therefore, for temperatures below 150° , be, in the case of acetic acid (also in that of nitric peroxide, which is similar), some cause (different from the mere approximation of the molecules by pressure, which at high temperatures accounts for the high vapour-densities at saturation) operating to increase the density. This can be no other than a *chemical* cause, and is probably due to the combination of some of the molecules by pairs, or, perhaps, partly into more complex molecules.

There are other arguments besides the one put forward here; and for these, and for the light thrown by the analogy of the behaviour of the dissociating compounds, the original paper must be seen. The general result from all the considerations adduced is, that for *stable* substances the difference between the liquid and the gaseous state is not one of kind but of degree; that the phenomena accompanying the vaporisation of a single stable body in the liquid state presents no evidence, from the study of the vapour, in favour of the existence of complex molecules in the liquid; that, on the other hand, in the cases of acetic acid and nitric peroxide, there is evidence of the formation of complex molecules in the vaporous and in the liquid forms of these bodies; the complex molecules corresponding in some respects to molecules of an unstable, dissociable body.

The difference between the gaseous and the liquid condition of a stable body is thus referred to the greater approximation to each other of the gaseous molecules, and to the consequent increase in their attraction for one another, which is known as cohesion.

There is no doubt of the wonderful accuracy with which the equation $p=bT-a$ expresses the results of experiment for four of the bodies examined, *viz.*, ether, methyl- and ethyl- alcohols, and CO_2 ; and of the considerable deviation of the results of experiments from the predictions of this formula in the cases of nitric peroxide and acetic acid, and probably for formic acid and other bodies. The explanation given above of the differences between these two sets of cases involves the separation of bodies into two classes, to one of which the equation applies accurately, and to the other not at all.

Perhaps it will be found that even here it is a question of degree and not of kind; that bodies differ from one another in reference to the degree to which they conform to the rule expressed by the above equation in the gas-liquid state; that there is, in fact, a perfect gas-liquid state, as there is a perfectly gaseous state; and that many bodies can be

found which conform almost perfectly to the gas-liquid condition, others less perfectly, while others again deviate from it in a very marked manner.

Molecular Weight of Nitric Peroxide by Raoult's Method—Ramsay.

Raoult has of late years,¹ by a long series of investigations, succeeded in perfecting a method by which the molecular weights may, in a large number of cases, be determined by observations of the degree of temperature by which the freezing-point, either of water or of some other substance, is lowered by the solution of a given quantity of the solvent.

In the case of acetic acid as the solvent, the freezing-point of this, when perfectly anhydrous and pure, is 16.68° ; dissolve in a given weight of acetic acid a known small quantity of the substance whose molecular weight is required; observe the melting-point of the acetic acid with the addition of this substance; it will be found lower than 16.68° ; note the difference; and assuming, as we may, that the lowering is proportional to the small quantity of the substance dissolved, calculate the lowering of the freezing-point for the solution in acetic acid of 1 part in 100 parts of the acid; this amount multiplied by the molecular weight in almost all cases in which the molecular weight is known is 39. This is called by Raoult the molecular depression for acetic acid; assuming now, in any case, the molecular depression to be 39, it is seen that by noting the depression produced by a given small weight of a substance in acetic acid the molecular weight of the substance can be determined.

Ramsay has applied this method² to find the molecular weight of nitric peroxide at about 16° , by dissolving small weighed quantities of the liquid in acetic acid, and finds in a series of experiments that the molecular weight of the peroxide is always near 92; and that the relative number of molecules of the peroxide in a given volume of acetic acid may be decreased from 8.97 to 0.92 without materially altering the molecular weight; no dissociation therefore of N_2O_4 takes place on dilution.

Experiments giving Points on the James Thomson Sinuous Curve.

Experiments have been repeatedly made in reference to the anomalous condition of a liquid when in certain circumstances it can be raised in temperature above, and often considerably above, its boiling-point without entering into ebullition. This state of a liquid has been the subject of special examination by Donny,³ by Dufour,⁴ and by Gernez.⁵ In the case of some experiments of this kind there is not only the liquid but the vapour above the liquid at a temperature above the boiling-point of the liquid, while the pressure of this vapour hardly exceeds the atmospheric pressure, and no liquid distils. These are cases where for the temperature (above the boiling-point) the pressure of the vapour is less than the vapour-pressure normally belonging to that temperature. We have here, therefore, points on that part of the sinuous curve which is convex to the axis of volumes. Such a point, as Ramsay and Young

¹ *Ann. Chim. Ph.* [5], 20, 1880; 28, 1883; and [6], 2, 1884; 4, 1885; 8, 1886. The *Agenda du Chimiste* for 1888 contains a summary of the principles and practice of M. Raoult's method by himself, p. 475.

⁴ *Ibid.* [3], 68, 1863, p. 370; [4], 6, 1865, p. 104; and 16, 1869, p. 470.

⁵ *Ibid.* [5], 4, 1875, p. 335; and 7, 1876, p. 113.

have shown, can be obtained at constant temperature by diminishing pressure, a case of which is a point on the isothermal, for 181.4° , of alcohol.¹ Other examples are methyl alcohol, liquid SO_2 , liquid NH_3 , heated with their vapour to temperatures considerably above the temperature at which the vapour-pressure is, in the static method, in equilibrium with the atmospheric pressure² (this Report, 1886, p. 13).

Points on the upper part of the sinuous curve—concave to the axis of volumes—are points at which the pressure is in excess of the vapour-pressure for a given temperature; these points are reached in cases where a space is supersaturated with vapour. In 'Nature,' March 1, 1880, Mr. John Aitken gives an abstract of a paper read by him at the Royal Society of Edinburgh on February 6 the same year. In this remarkable paper, 'On the Number of Dust Particles in the Atmosphere,' he shows that when an expansion by a stroke of the piston of an air-pump is made in the air saturated with moisture in the receiver, a fog is formed by the dust particles acting as nuclei to small droplets of the water precipitated on them through slight loss of heat and lowering of temperature consequent on expansion against pressure; but that if the air be by filtration through cotton-wool freed from the greater part of the dust particles, after allowing the fog produced by the stroke of the piston to subside, subsequent fogs so produced will at length become slighter, until a small stroke (and then a larger stroke as the operation is repeated) ceases to produce a fog or any deposition of water in the liquid state; the air is thus to a greater or less extent supersaturated with aqueous vapour. If all the air-dust has settled, some points on the upper part of an isothermal curve of water are thus obtained, at which the pressure is greater than the vapour-pressure of water at that temperature.

All points on this sinuous curve represent unstable states of equilibrium, so that if the stroke of the piston is made with a jerk a copious shower is produced in the dust-free air.

Properties of Bodies for which $p=bT-a$.

Professor G. F. Fitzgerald³ discusses the 'thermodynamic properties of substances whose intrinsic equation is a linear function of the pressure and temperature.' The intrinsic equation is the equation $p=bT-a$, in which a and b are functions of the volume only; and the conclusions he draws are the following:—

(1) The specific heat of the substance at constant volume is independent of the pressure.

(2) The internal energy of the substance is the sum of two terms, of which one is independent of the pressure, and the other independent of the temperature.

(3) The entropy of the substance is the sum of two terms, of which one is independent of the pressure, and the other independent of the temperature.

Isopyknics.

The above name is given by Wroblewski⁴ for lines representing the relation between pressure and temperature when the density is kept

¹ *Phil. Trans.* 1886, Part I. plate 3.

² *Reg. Mém. t. xxvi. p. 645.*

³ *Proc. Roy. Soc.* 42, 1887, p. 50.

⁴ *Wiener Monatsheft f. Chemie*, 1886, p. 383; and *Wied. Ann.* 29, 1886, p. 428.

constant. These lines are obviously the same as Ramsay and Young have investigated; for if the density of a given mass is constant, its volume is constant. Isopyknic lines are therefore isochoric lines, and Wroblewski is attacking precisely the same problem as Ramsay and Young have apparently brought to a successful conclusion for several widely different substances by means of their own laborious and skilful experiments. Wroblewski calculates their data by means of Sarrau's equation, which, however well it may apply to portions of the data for CO_2 , is not to be taken as a rigorously proved theorem which can enable one to dispense with direct experiment. A criticism of Wroblewski's method and conclusion is given by Ramsay and Young in 'Philosophical Magazine,' 23, 1887, p. 547.

Compressibility of Liquids.

Amagat, in the course of his examination of the effect of pressure on gases, found¹ for the gases he examined, including CO_2 for low temperatures as for high, when the pressure is very great, the following relation $p(v-a) = \text{constant}$; this relation holds good very approximately at ordinary temperatures, whether at these temperatures the compression condenses the gas to a liquid or not—whether or not the temperature is above or below the critical point. The higher the temperature the higher the pressure required beyond which the above relation holds; but at ordinary temperatures the pressure need not exceed from 400 to 500 atmos.; the constant a for all pressures above a certain number of atmos. and for the volumes corresponding varies with the gas or liquid and with the temperature.

Amagat's results, however, were obtained for gases mostly, and for CO_2 at temperatures not very much below their critical points. The problem is not the same when we take the case of water, mercury, or other liquids, the compressibility of which is slight, and for which the compression is usually measured by a special instrument, a piezometer.

In a previous paper² Amagat made a special investigation into the effect of variation of temperature on the compression of a variety of liquids, among them ethyl—chloride, bromide, oxide; methyl—and ethyl—acetates, methyl alcohol, ethyl alcohol, amyl alcohol, some paraffins; benzene, chloroform, carbon bisulphide, and acetone; the pressures not being greater than 37 atmos., the minimum temperature for each body being about 11° – 13° , and the maximum about 100° .

Again, Amagat has made recently³ a special investigation into the compressibility of water, and in particular into the effect of compression on the point of maximum density. In some respects water behaves quite differently from all other liquids. Thus, as the pressure increases the coefficient of expansion *increases*, more and more slowly at higher pressures, but, at pressures up to and beyond 200 atmos., rather rapidly; at about 3,000 atmos. the coefficient of expansion ceases to increase, and, probably, at higher pressures, it diminishes, as is the case with other liquids. Between two given pressures the compressibility *diminishes* as the temperature rises, contrary to the behaviour of other liquids.

Meanwhile, as pressure is continuously increased, the point of maximum density is lowered till at 200 atmos. it is nearly 0° ; at 700 atmos. it

¹ *Ann. Chim. Ph.* 22, 1881, pp. 319-397.

² *Ibid.* 5, 11, 1877, p. 520.

³ *C. R.* 104, 1887, p. 1159; 105, 1887, p. 1120; and *C. S. J. Abs.* 1887, p. 695, and 1888, p. 215.

is below 0° . No liquid besides water showed in Amagat's experiments any sign of a point of maximum density; the peculiarities associated with this point in the case of water seem to cease at pressures above 3,000 atmos., and water at higher pressures behaves like other liquids; the liquids examined were ether; methyl, ethyl, propyl, and allyl alcohols, ethyl chloride, bromide, and iodide, carbon bisulphide, and phosphorous chloride.

Solidification of Liquids by Pressure.

Of the many liquids subjected to great pressure, Amagat¹ had not succeeded in solidifying one; at last the compound C_2Cl_4 was found to solidify at a great pressure, the temperature of solidification rising with increase of pressure; the temperature of solidification is the freezing-point of the liquid and the melting-point of the solid; in the exceptional case of water, which *expands* on freezing, the melting-point of ice was expected by theory and found by experiment to be *lowered* by pressure; in the case C_2Cl_4 , the temperature of solidification, which at atmospheric pressure is much below 0° , rises with increased pressure as Amagat found, the solid having a very distinct crystalline structure. The following are among Amagat's results for pressures and freezing-points of this body:—

Pressure in atmos.	. . .	210; 620; 900; 1,160
temperature	. . .	$-19^{\circ}5$; 0° ; 10° ; $19^{\circ}5$

Benzene solidified at 22° under about 700 atmos. Amagat considers it not improbable that every liquid has a 'critical' temperature of solidification—*i.e.*, one above which no pressure, however great, will convert the liquid into a solid.

Compressibility of Solids and Liquids.

The general discussion of this problem up to his time, and experiments by himself on the compressibility of water, mercury, and of glass, brass, and copper, are given by Regnault.² In Tait's 'Properties of Matter' (1885) there is an historical account, including and supplementing that by Regnault, a critical discussion of theory and experiment on the subject, and of advances in it made since Regnault's time.

The reader interested in this part of the subject cannot do better than consult this excellent summary by Professor Tait.

References are here given to papers by Oersted, Perkins, Colladon, and Sturm, Poisson, Aimé, before Regnault's researches; also to Wertheim, Grassi; to a paper by Cailletet, and one by Pagliani and Vicentini.

To these must be added papers by Voigt, Röntgen and Schneider, Braun, and Tait.³

In a paper by Tait, of Dec. 1887, the ultimate loss of volume of water under infinite pressure is estimated at about 25 p.c.; in a paper of March 5, 1888, the same author finds the compressibility of lead-glass per atmosphere as $\cdot 0_527$; and the increase of compressibility per degree Centigrade as $\cdot 0_72$.

Melting-points—Carnelley and Carleton-Williams.

In the application of heat to solid bodies which are not decomposed by heat at the temperatures employed, the effect after reaching a certain temperature is that the body will change its state, either by liquefying or volatilising; or both effects may take place together, especially in a case such as that of iodine, where there is not a great interval between the point of liquefaction, or melting-point, and the boiling-point.

Both of these points, however, are dependent on external pressure; the effect of pressure on the boiling-point is very considerable compared with the effect on the melting-point, which is in general hardly appreciably altered by a great alteration of pressure. But whether a substance shall volatilise without melting depends on the external pressure.

The experiments of Carnelley are concerned with the melting-points of bodies which melt at atmospheric pressure; a multitude of cases of inorganic bodies, chiefly compounds, have been determined with great care and accuracy, and the experiments and results published in a number of papers in the 'Trans. of the Chem. Soc.'¹ and in papers contributed to the 'Phil. Mag.' and the 'Proc. Roy. Soc.'

In many cases a knowledge of Carnelley's melting-points makes it possible to determine within moderate limits the boiling-point of a body when this is high, without recourse to an air-thermometer; this is done by finding two bodies, near to one another in their melting-points, one of which is and the other is not fused in the vapour of the boiling substance. This is, in fact, the method which was used by Carnelley and Carleton-Williams² for the approximate determination of the boiling-points of some salts and other bodies. By establishing relations connecting the melting-points with the atomic weights in the case of elements³ and of compounds, Carnelley has predicted melting-points of bodies which had not been determined, and found a very fair agreement between the calculated and the afterwards-observed temperatures.

A noteworthy example of this is in the cases of beryllium chloride and bromide, the melting-temperatures of which they observed and found to agree⁴ well enough with what they should be if calculated for the formulæ BeCl_2 , BeBr_2 , but to be enormously too high for the formulæ BeCl_3 , BeBr_3 , or for these formulæ doubled. It is evident from this example that Carnelley's method is an additional and valuable aid towards deciding between proposed formulæ of metallic chlorides and bromides, and so between two proposed numbers for the atomic weight of an element and the molecular weight of a compound.

Effects of Pressure—Solids.

The effects of great pressure on solid bodies in the state of powder have been examined by Spring in a series of investigations extending over several years, accounts of which have been published from time to time.¹

The bodies being taken in the state of powder, and the apparatus used being capable of exerting a pressure of about 10,000 atmos., experiments were made on various bodies, elementary and compound. The effects may be classed under two heads, mechanical and chemical.

As to the mechanical effects, the following metals—*lead, bismuth, tin, zinc, aluminium, copper, antimony*—taken in the form of powder or filings, when subjected to pressures up to 6,000 atmos., were completely welded into a homogeneous mass of the specific gravity of the metals in block, sometimes with crystalline fracture, but with no trace of powder or filings visible; spongy *platinum* gave a block with shining metallic surface exhibiting a dull fracture, and perfect union was not obtained at any pressure; similarly with amorphous carbon; while graphite powder was welded at 5,500 atmos. into a compact mass of solid graphite. Similar results in general were obtained with metallic oxides, sulphides, salts, *e.g.*, chlorides, bromides, iodides, sulphates, nitrates, carbonates, thiosulphates, phosphates, and on other bodies; with most of these, though not with all, the welding process took place, although in not a few cases the welding was incomplete. It was found in subsequent experiments that welding requires time, and that the completion of a welding process was favoured by several conditions, such as amount of pressure, the time during which pressure was applied, and temperature, a rise of temperature favouring the process. A substance difficult to weld was found, on breaking it up, to be most imperfectly coherent in the interior; and on powdering it again and renewing the pressure again and again the welding can be made complete. Generally, the harder the substance the more difficult it is to weld it; if a body exist in allotropic modifications—as, *e.g.*, sulphur—the effect of pressure is to produce a coherent mass having specific gravity equal to that of the densest variety. The welding of a powder is in some respects analogous to the liquefaction of a gas by pressure; the particles of the powder are brought into closer contact and within each other's sphere of cohesion, and then unite like drops of water. Although the temperature is hardly raised in the experiments, some metals at very high pressures flow and ooze out of the joints of the apparatus. It will sometimes happen that no welding takes place at a very high pressure, but on still further increasing the pressure the process is effected.

As to the formation of alloys by pressure, it was found that Woods' metal was formed by submitting to a pressure of 7,500 atmos. a mixture of filings of bismuth, cadmium, and tin in the required proportions. Rose's alloy of lead, bismuth, and tin was obtained in a similar manner.

¹ *Wied. Ann.* [5], 22, 170; *Bull. Acad. Belg.* 1880 [2], 49, 323; *Abs. Jahr. f. Min.* 1882, 1, R. 42; *Ber.* 1882, pp. 15, 595, *Ber.* 1883, pp. 16, 324, 999, 2723; *Ber.* 1884, 17, pp. 1215, 1218; *Bull. Soc. Chim.* 44, p. 166; 46, p. 299; *Ber.* 1885, 18, R. 597; *Ber.* 1886, R. 728; *Ber.* 1887, 20, R. 358; *Zeitschr. f. phys. Chem.* 1, 231. And abstracts in *C. S. J.* 1881, p. 498; 1882, pp. 273, 921; 1883, pp. 650, 904; 1884, pp. 256, 949, 959; 1887, p. 332.

Ordinary brass was got with difficulty by repeatedly submitting a mixture of zinc and copper filings to great pressure.

Spring lays down the rule that 'matter assumes that condition which corresponds to the volume it is made to occupy.' Thus when two bodies can by their union or interaction produce one of less volume or greater density, this will be produced by great pressure; and he explains by this the readiness with which Woods' and Rose's alloys are formed as contrasted with the formation of brass by great pressure. At 6,500 atmos. arsenides of lead, copper, and silver are formed from the elements in the same way; and the following sulphides, viz., of Mg, Zn, Fe'', Cd, Bi, Pb, Ag, Cu, Sn, and Sb, by repeated compressions. Spring found that the extent to which the formation of sulphide is carried in this process depends on time as one condition; by the lapse of time alone more of the sulphur and metal combining to form more of the sulphide.

Chemical Actions by intense Pressure.—Solids.

A dry intimate mixture of sodium carbonate and barium sulphate being submitted to intense pressure, double decomposition occurs to a considerable extent. A double decomposition also occurs under similar circumstances with a mixture of dry powdered sodium sulphate and barium carbonate; and when the resulting compressed cylinder was again powdered and submitted to intense pressure, and the process repeated several times, the substance being maintained for some time under pressure, the formation of barium sulphate increased to about 80·5 per cent., which seemed to be the limit.

The Transition-point.

J. H. Van 't Hoff calls by the name 'transition-point' that constant temperature at which a chemical change can begin and continue, and compares it to the melting-point of a solid in its theoretical relations. Thus, if there is a transition-point in a chemical action, this point must be dependent on the pressure in such a manner that if the change is accompanied by decrease of volume, as in the melting of ice, the transition-temperature should be *lowered* by increased pressure. As an example, Van 't Hoff and Spring take the case of a double acetate of calcium and copper.¹ At ordinary pressures the double-salt, which is blue, is decomposed into its component salts at 75°, and this change is accompanied by diminution of volume, as in the melting of ice. Therefore increase of pressure should lower the transition-point, and therefore promote the formation at a lower temperature than 75° of the separate salts from the double salt. Now the cupric acetate by itself is green, and the transition can therefore be observed by the change of colour. At 6,000 atmos., and temp. 16°, the finely powdered double acetate became a marble-like crystalline mass, but showed no sign of decomposition; at 40° a quantity of the mass liquefied; on relieving the pressure it became all solid, the dark blue had changed for the most part to green, and there was found a coating of copper round the sides of the containing vessel. At 50° the action was more rapid. It was found also that the decompo-

¹ *Bull. Acc. Belg.* 49, 344; *Zeitschr. f. phys. Chem.* 1, 227; *C.S.J. Abs.* 1888, p. 341; *Rec. trav. chim.* 6, 91; *Ber.* 1887, R. 276, 311.

sition could take place at ordinary temperatures by the application of sufficient pressure during a sufficiently long time.

In a further communication, Van 't Hoff¹ mentions that at his suggestion Spring had subjected the double acetate to high pressures at varying temperatures, and adds that by prolonging at 16° the pressure of 6,000 atmos. evidence of decomposition is readily recognisable. Van 't Hoff points out that determinations of the minimum pressure required to produce reactions of this kind, together with measurements of the resulting changes of volume, will make it possible to express in kilogram-metres the absorption of energy involved in the reaction, and conversely the liberation of energy resulting from the reverse change.

Report of the Committee, consisting of Sir F. J. BRAMWELL, Mr. E. A. COWPER, Mr. G. J. SYMONS, Professors G. H. DARWIN and EWING, Mr. ISAAC ROBERTS, Mr. THOMAS GRAY, Dr. JOHN EVANS, Professors LEBOUR, PRESTWICH, HULL, MELDOLA, and JUDD, and Mr. J. GLAISHER, appointed for the purpose of considering the advisability and possibility of establishing in other parts of the country observations upon the prevalence of Earth Tremors similar to those now being made in Durham.

DURING the past year a good deal has been done in the way of devising, constructing, and testing new forms or modifications of old forms of earth-tremor-registering instruments. Professor Milne in Japan and Dr. Holden, of the Lick Observatory in California, have instituted systems of earthquake observations, the former employing instruments of various kinds, chiefly of his own invention, and the latter using Professor Ewing's duplex seismograph. Professor Ewing has, however, recently been engaged in materially improving this instrument and also in perfecting a cheaper time-recording apparatus with a special view to numerous observers stationed in many parts of the country. He has also quite recently brought out a new sensitive electric seismoscope. Mr. E. A. Cowper has described at the present meeting of the Association yet another seismoscope, of entirely new construction, specially adapted for recording vertical motion. The North of England Institute of Mining and Mechanical Engineers have continued the series of observations on the coast of Durham at Marsden, and have now three instruments at work there, including a form of cheap recorder constructed from the designs of Mr. M. Walton Brown. That institute has issued an elaborate preliminary report on these instruments (1888).

An important observing station, with adequate funds, promises to be instituted by Mr. C. Davison and Professor Poynting at Birmingham.

Considering that so much is being done with the object of securing suitable forms of instruments, and that these investigations are still incomplete in many ways, the Committee feel that it would be premature for them to select and recommend any special recorder at present. They wish, however, to emphasise the view that, whilst carefully finished, highly sensitive, and necessarily expensive seismoscopes made to record

¹ *Ber.* 20, R. 311, 1888; *Rec. trav. chim.* 6, p. 137; *C. S. J. Abs.* 1888, p. 404.

with as much accuracy as possible the time, form, and intensity of each set of tremors are very desirable, and indeed indispensable, yet only a comparatively small number of such instruments would be required in a general scheme of seismographical observatories. Such instruments, moreover, could only be used with effect in carefully selected situations, and otherwise under very special conditions. On the other hand, comparatively rough, *cheap*, and easily used instruments, which could do little more than afford fairly accurate time-records, would be required in large numbers, and must form a most important portion of such a scheme.

Under these circumstances the Committee are glad to hear that the observations and trials of instruments above referred to are being continued in the north of England and elsewhere. They trust that special attention will be paid to the question of suitability in selecting the localities and, generally speaking, in considering all the local conditions of the observing stations.

Earth-tremors appear to be of frequent occurrence, and should be recorded, but the Committee propose to take no immediate action. Next year they hope to be in a position to present a report containing definite recommendations. In asking to be reappointed they hope that Mr. M. Walton Brown, who has conducted the observations in Durham, may be added to the Committee.

The Relations between Sliding Scales and Economic Theory.

By L. L. PRICE, M.A.

[A communication ordered by the General Committee to be printed *in extenso* among the Reports.]

THE treatment which I have ventured to give in this paper to the subject I have chosen—the Relations between Sliding Scales and Economic Theory—will, I am afraid, appear at the outset to be confined within very narrow and definite limits. It will seem to involve nothing more than an inquiry into the connection which exists, or may exist, between a practical expedient adopted with some success in some few industries for the regulation of wages, and that limited—although contentious—part of theoretic economics which is concerned with the determination of the rate of wages. And, narrow and definite as these limits may appear, I propose to circumscribe the subject still further; for not only do I intend in the main to limit my consideration of sliding scales to their employment in the regulation of wages, but I purpose also to confine it for the most part to the form in which they have, as a matter of actual fact, been employed. By sliding scales, then, I mean in the main certain expedients which have been adopted in the coal and iron industries as the result of an agreement between two opposing combinations of masters on the one hand and of men on the other, in accordance with which fluctuations in wages have followed, we may almost say automatically, on changes in the selling prices of the coal and iron. And by economic theory I mean for the most part that theory which is known by the name—partial and erroneous as may be its application—of the abstract or deductive method. Within these narrow and definite limits I propose to examine the nature of the relations between sliding scales and economic theory.

And yet, narrow and definite as are the limits I have prescribed, the subject almost of necessity presents some points of wider interest and of larger importance than might at first be supposed. It necessarily involves the examination from an economic standpoint of the nature and consequences of those combinations which seem to be occupying, and to be destined to occupy, a more and more prominent position in the industrial world as time moves on. For the adoption and the continued observance of a sliding scale appear to presuppose some sort of organised representation on either side; and organised representation is but another name for combination.

The subject, again, almost of necessity compels the consideration of some of the chief changes which have taken place in the economic theory of wages, as it appears to have been conceived by Ricardo, and as it is now generally accepted. And, lastly, it has certainly some indirect bearing on the relation between economic theory and practice.

If I may be permitted to do so, I should like to preface my examination of the question by a brief account of the circumstances which originally induced me to attempt it. Some months ago there appeared in the pages of a periodical—the name of which would, I imagine, be of little or no interest to the members of the Section, and I therefore withhold—two able and indulgent criticisms on certain views I had ventured to put forward in a recent publication¹ on the subject of this paper. These criticisms led me to reconsider the attitude I had adopted with some little care, and it is the general results of that reconsideration which I venture now to submit; and I have given this explanation in order to afford some excuse at the outset for the egotistic form which the paper will take.

The first of these critics—who, I may remark in passing, was a strenuous adherent of what I suppose we must call the ‘historical’ method—observed that the work he was criticising, which contained these views, was the ‘outcome of common sense working upon historical and statistical material *unaided*² by economic theory.’ The other critic, who lent his support rather to the abstract or deductive method, rejoined that the ‘*neglect*’² of that theory was the ‘one grave defect’ of the book. Now, it appeared to me, perhaps not unnaturally, that both these criticisms were wrong. It seemed to me that it was impossible to discuss with adequate completeness the facts and the principles of sliding scales ‘unaided’ by economic theory; and on the other hand I hoped that I had not been guilty of the unpardonable sin, as it would seem to me, of the ‘neglect’ of that theory. I was firmly of opinion, in opposition to my first critic, that such knowledge of theory as I might have possessed had ‘appreciably helped’ me in the discussion of sliding scales; that it had ‘supplied’ me with ‘points of view;’ that it had given me ‘guidance in the arrangement of material;’ and that the ‘facts of real life and the theories of economists’ had not ‘been kept, as it were, in two separate compartments of’ my ‘mind.’ And yet I could not agree entirely with my other critic when he asserted that ‘Political Economy does supply the principle’ on which an arbitrator should act, or a sliding scale proceed; and that that principle was that he or it should endeavour to award such wages as would be obtained if ‘combination on either side were absent.’ This criticism indeed appeared to me to be nearer the truth, as I held it, than the other, but I did not think that it had entirely

¹ *Industrial Peace.*

² The italics are my own.

succeeded in reaching it. And so I was led to reconsider the attitude I had originally adopted.

And here I am afraid that I can only explain my meaning and define my attitude by quoting the three passages in the book to which my critics referred where the relation of economic theory to methods of industrial conciliation is considered. Nor will these quotations be irrelevant to the strict subject of this paper, the relation of that theory to sliding scales: for, on the one hand, the starting-point of a scale must almost necessarily be an agreement obtained by conciliatory methods—by conciliation that is, or arbitration; and, on the other, the principle which has as a matter of fact, I believe, been invariably taken as the basis of a scale in industrial matters—the concurrent variation of wages and prices—is also the principle to which recourse has generally been had at boards of conciliation or courts of arbitration.

The first of these passages occurred at a place¹ where the nature of what I had ventured to call 'irregular negotiations' between masters and men in industrial disputes was examined. The passage ran in these terms: 'Nor, be it noticed, does there seem to be any economic standard which can be called into requisition in such disputes, for, as Professor Sidgwick has pointed out, where two combinations meet one another, political economy is perforce silenced.'

In the second and longest passage² it was argued that the 'principle' on which an arbitrator should act in adjusting industrial disputes 'could hardly be supplied by Political Economy.' . . . 'As Jevons has shown in his "Theory of Political Economy," in all bargains about a single *indivisible* object'—and I lay special stress, for reasons which will appear later, upon the word *indivisible*—'there may arise a "deadlock" because neither party can read the mind of the other, and discern the exact length to which it is prepared to go in pushing demands or accepting concessions. Nor indeed, did they possess the gift of clairvoyance, would the problem be necessarily solved. For even then there might be no definite point fixed in the mind of either. After alluding to this passage in his "State in Relation to Labour," he' (*i.e.*, Jevons) 'proceeds to point out that the existence of *indivisible* combinations in trade disputes'—and here again I would emphasise the word *indivisible*—'usually reduces them to a bargain of this "indeterminate" nature. To avoid a strike it may be the interest of either party to relinquish, or at least to relax, its demands; but theoretic economics cannot resolve the problem. It is, in mathematical phraseology, "indeterminate."'

The third and last passage occurred³ where the introduction into a sliding scale of such elements as the cost of materials and the state of the labour market was under consideration. 'From an economic point of view indeed,' it was argued, 'there is considerable reason for having regard to them, but it is the traditions of the trade which are of the greatest importance. For the existence of combinations on either side banishes, as we have noticed, to a very great extent all economic considerations, so far at least as the determination of the exact basis of the settlement is concerned.' And then, later on in the same paragraph, it was urged that 'the negotiations into which' the two parties 'enter can hardly be reduced to a question of pure economics, nor is there any economic touchstone which can be brought into requisition to decide the

matter.' And then the next paragraph began with these words:—'In a certain sense, indeed, it may be said that the regulation of wages by selling prices does rest upon an economic basis, however the particular details of that basis may be arranged.'

These, then, are the three passages to which my critics seemed to refer; and I should be inclined to summarise the argument to which they were intended to give expression in some such way as this. What I maintained was that, while the general nature of the principle on which a sliding scale may be based or an arbitrator proceed may, and indeed must, possess an economic complexion, yet the particular application of that principle—the special relation between wages and prices adopted as the starting-point of a scale—is not strictly determinable by economic theory. A treatise on sliding scales cannot then, it seems to me, be written 'unaided,' as one of my critics declares, by economic theory; and yet it is none the less true to maintain—in opposition to my other critic—that 'theoretic economics' cannot resolve the problem involved in the determination of the *exact* basis of a scale.

For what is the fundamental assumption of 'theoretic economics'? The answer which would, I imagine, be at once returned to this question would be, that the fundamental assumption of almost any scheme of theoretic economics is competition. That competition, indeed, may be hindered in its action by qualifying circumstances—by the *vis inertiae* of custom or some other obstacle; but we may nevertheless maintain that the hypothesis which presents itself at the outset before these qualifying circumstances are taken into consideration—the hypothesis which is revealed in the last analysis when these circumstances have been successively abstracted—is, undoubtedly, pure competition. The term 'competition,' however, stands in need of fuller explanation; for, for the purposes of 'theoretic economics,' it seems to me that the objects or interests about which the competitive forces play must be, in theory at least, susceptible of continuous subdivision. This is what I meant when I followed Jevons in arguing that 'the existence of *indivisible* combinations in trade disputes usually 'reduced' them to a bargain of 'an indeterminate nature.'

The proposition just laid down seemed to me to admit of more than one easy and simple test. We might take, for instance, Jevons' own conception of 'final utility.' Few economists, I imagine, would deny that that conception is now an accepted part of economic theory, and that it is one of the most fertile conceptions of modern economics. There are signs of its extension—along with the increasing amalgamation of the theory of exchange with that of distribution—from the theory of exchange of material commodities to that of exchange of services. It has been applied to the determination of interest; and it may, I suppose, be said to be connected with the theory of rent. But it cannot, I imagine, be accepted, save on the assumption enforced by Jevons himself,¹ that 'more or less of a commodity' can 'be had down to infinitely small quantities.'

Take once more the law of Diminishing Return—the overthrow of which would, as Cairnes once pointed out,² involve the rewriting of the greater part of economic theory—and what do you find? Here again the

¹ *Theory of Political Economy* (2nd edition), p. 130.

² *Logical Method* (2nd edition), p. 36.

assumption seems to me to be fundamental that 'doses' of capital and labour—to use the elder Mill's suggestive expression—can be applied to the cultivation of land in infinitely small quantities, and that the returns to those doses, when a certain point of cultivation has been reached in a certain stage of civilisation, diminish also *cæteris paribus* by infinitely small degrees.

Or take again—though I do not lay much stress on this—one variety of what I may perhaps call the application of the 'graphic method' to economics. It seems to me—though I speak, I confess, with some hesitation—to be impossible to represent, as some economists have done with conspicuous success, economic theorems by geometrical curves unless we assume the possibility of division into infinitely small quantities.

This possibility, in fact, is the underlying basis of any theory of competition, and in the final analysis of any such theory it cannot fail to appear. The theory may indeed be only hypothetically true; although for my part I must confess that I am inclined to believe that it is a more accurate and serviceable representation of fact than is sometimes maintained. The conditions, again, of the hypothesis must always be remembered; and it may be the case in some instances that the quantities into which the commodity or service is capable of division may only be infinitely small in comparison with the great mass of the commodity or service under consideration. But this possibility does not prevent the theory from being hypothetically true; nor, on the other hand, does it obviate its failure to apply in its entirety to cases where this capacity of infinite divisibility is lacking.

One of these cases occurs whenever a combination of sellers meet a combination of buyers. The commodity or service offered by either party in exchange for that supplied by the other is *ex hypothesi* whole and indivisible. There may indeed possibly be—as we shall endeavour to illustrate later—a maximum as well as a minimum limit beyond which it may respectively be the interest of neither party to go. But no theory of competitive economics—based as it is on the possibility of infinite subdivision—will enable you to determine the precise point between these two limits at which it is for the joint interest of the two parties to stop; for the commodities or services they are exchanging are, by the very terms of the existence of the combinations, incapable of that infinite subdivision. On the one side you have, roughly speaking, in the case of a sliding scale a combined mass of labour offered for sale; on the other, you have a combined mass of remuneration, be it expressed in terms of nominal or real wages or earnings—and by the very conditions of the combinations, neither of these two masses is capable of infinite divisibility. If a combination of buyers alone, or a combination of sellers alone existed, this capability might indeed be impaired, but it would not be paralysed. The one commodity or service offered in exchange would retain it, and the other would lose it. And hence it is, I suppose, that Professor Sidgwick has discussed¹ as a part of economic theory the action of monopoly or combination. But the combination he considers is, as he himself expresses it, only one-sided; and the combinations in connection with a sliding scale, which we are now discussing, are found on both sides. And yet the existence of these combinations seems, we must remember, to be a necessary condition of successful conciliation, or arbitration, or sliding

¹ *Principles of Political Economy*, Book II ch x.

scales ; for there must be organised representation on either side if there is to be any authoritative or binding agreement, and organised representation is but an alternative expression for combination.

Nor does my critic seem to me to succeed in showing a way of escape from this conclusion ; and, if I might be allowed to put my own interpretation upon his language, and to supply the missing parentheses, I imagine that the difference between us might be reduced to the narrowest limits, even if it did not disappear altogether. Let me quote his words:—‘As a matter of fact,’ he argues, ‘political economy does supply the principle—which is, that the arbitrator should endeavour to award such wages as would be obtained if combination on either side were absent. If he fixes them appreciably above or below this level, economic theory shows that his award will have very soon to be revised. So, too, economic theory shows that if a sliding scale has the effect of making the wages paid under it differ much from competitive wages it must break down.’

Now, looking at the matter for a moment from a practical standpoint—although, indeed, I freely confess that for the immediate purposes of this discussion this mode of regarding the question is chiefly important for the side-light it may throw upon the theoretical aspect—but adopting for the moment this practical standpoint, I am afraid that my critic’s argument does not carry us very far. For where, let me ask, is the unhappy arbitrator to discover this ideal standard ? If he confines his consideration within the limits of the two organisations which are represented before him, he manifestly can discover no such standard. He cannot arrive at anything save a particular relation between wages and prices, which is held by both parties to be fair ; and the fact that they both consist of combinations whose express purpose is to secure better terms than could be obtained by individual competition, establishes a strong presumption against the belief that any standard could have become traditional which was determined merely by the influences affecting competitive wages. Nor, for the very same reason—and of this point the history of industrial conciliation supplies more than one striking and instructive illustration—will they be inclined to accept an appeal to the standard of wages prevailing outside the limits of their own, or at least of some, combination ; for by doing this they would virtually nullify the *raison d’être* of their own organisation.

Nor, indeed, is it possible for the arbitrator himself to penetrate, as it were, beneath the stratum of combination and to reach that of pure competition. Within the limits of the combinations before him he cannot do this ; for he cannot strip off so much and declare that what is left is what would be the case ‘if combination on either side were absent.’ He cannot, in fact, isolate the competitive wage from the action and interaction of the two combinations. The rate of wages is the result—to use a metaphor with which students of logic are familiar—of chemical rather than mechanical action, and the effects of the causes are intermixed.

Nor, again, can he succeed in this aim by having recourse to the labour market outside these limits ; for he cannot really pass beyond the influence of the forces originating within them. The so-called competitive market itself must be influenced by the action of the combinations. If you have a strong buyer and a strong seller—and what are combinations but strong buyers and sellers ?—at any particular time in a market, they will, for good or for evil, affect the market price ; and if the permanent condition of affairs be that of a strong buyer confronting a strong seller,

they will, for good or for evil, exercise a permanent influence on the market price, however wide the area of the market be. And a 'market,' in the economic sense, we must remember, may cover a very large area.

This conclusion conducts naturally to the consideration of the question from the point of view which is at present of the most immediate importance to us—that of theoretic economics. And here I am prepared—and the previous course of the argument has, I think, tended to this result—to accept my critic's opinion, subject to my own interpretation and commentary. I readily allow that, if an arbitrator fixes wages at too great a distance above or below a competitive 'level' in time the action of what we may perhaps call *external* competition—modified, indeed, and retarded by combination—will bring about a reversal of his decision. I do not see, indeed, how he is to ascertain this competitive 'level' save by examining into the past history or present condition of a market—be it within or be it outside of the limits of the organisations represented before him—where combinations have influenced wages. Nor do I think that it would be easy to determine the exact distance which would be 'appreciable' enough to upset his award. But, subject to these reservations—the latter of which is, I admit, more important from the practical than from the theoretical point of view—I accept my critic's conclusion. And in the same way it may be the case—and I for one would not question it—that 'if a sliding-scale has the effect of making the wages paid under it differ much from competitive wages it must break down.' But here again it is true—from the standpoint alike of theory and of practice—that these 'competitive wages' themselves will be influenced by the reflex action of the two powerful combinations; and that the exact amount of difference which, for the purposes we are now considering, ought to be characterised as 'much' would be hard to determine.

The truth, as I conceive it, may be expressed in some such way as this: combinations cannot entirely free themselves from competitive influences, any more than competition can nullify the presence and action of combinations. Competition prescribes, as I think, at any particular time in a market what I will follow Roscher in calling a maximum and a minimum limit to wages; but 'theoretic economics,' based as they are on two-sided, or at any rate on 'one-sided,' competition, cannot determine the exact point between these two limits at which two combinations will, or should, agree on a price. 'The existence,' then, 'of combinations on either side' does, as I have argued, 'banish' 'to a very great extent'—and I must add myself, though my critic does not in his quotation from me, this qualifying expression—it does banish 'to a very great extent' all economic considerations, *so far at least*—and here, again, I would emphasise the addition of this qualifying clause—'so far at least as the exact basis of a settlement is concerned.'

I do not intend to maintain, as my critic seems to imagine that I do, that 'by means of arbitration and conciliation and sliding scales the wages paid in a trade can be somehow or other removed from the arena of competition;' but I do maintain that it is impossible to determine by any theory, based, and based essentially, on the unrestrained freedom of any fresh combatant to enter the lists or of anyone already within the arena to withdraw—it is impossible to determine by any such theory the exact issue of the contest when, in place of this unrestricted freedom, you have the comparatively rigid and unvarying forces of two rival combinations.

Metaphors, however, are proverbially liable to break down at some important point; and therefore I will, at the risk of trespassing upon the patience of the Section, endeavour to make my meaning plain by an examination of the general nature of the change which has, I think, passed over the theory of wages in modern economics. The old theory of Ricardo¹—so much maligned and so often misunderstood—was, I imagine, so far true that, looking at the matter chiefly from what I may call a statical point of view, and remembering that Ricardo used the term ‘profits’ in what would now be regarded as a loose and inexact sense—making allowance for this, and looking at the matter chiefly from the statical standpoint—if you had a definite total amount of wealth produced, and a definite share of that total were taken for the landlords in rent, the remainder would be all that could be divided between the capitalists and the labourers, and if wages gained profits must lose. Looking at the matter, then, in this way, it would not be difficult to obtain from Ricardo an idea of what I will call the ‘competitive’ maximum limit of wages. That limit would consist in the amount of wealth left when the capitalists had secured the rate of profits prevailing in the country—the rate that is prescribed by the return yielded by the land on the margin of cultivation to the capital and labour applied to it.² Nor, again, would it be easy even now to discover any other ‘competitive’ minimum limit, as I will call it, than that presented in Ricardo’s idea of the cost of production of labour.

Wherein, then, we may ask, did he fail? He failed in neglecting to lay stress on the causes which might extend the maximum limit. Nay, he rather looked forward—and we cannot in fairness say that this pessimistic forecast was unwarranted by the circumstances of the times when the law of Diminishing Return seemed to be applying to England with terrible reality—he rather looked forward to a contraction than to an extension of the maximum limit. Neither he nor Malthus—as M. Leroy-Beaulieu has insisted with characteristically French epigrammatic force³—were ‘geographers.’ Their horizon—so far at least as the future was concerned—was to a great extent bounded by the circumstances of their own country, and it was in a large degree on those circumstances that they founded their generalisations of the future.

In the second place, Ricardo may be said, on the whole, to have failed by neglecting to give sufficient emphasis—and to repeat the emphasis from time to time at each successive stage in the argument—to the elasticity of the expressions, ‘the cost of production of labour’ and ‘the average rate of profits.’ It was, I suppose, to a large extent in consequence of this that he failed to examine the distance by which, at any particular time and in any particular condition of the labour market,

¹ So far, indeed, as Ricardo can strictly be said to have *formulated* any definite and complete theory of wages.

² And so Ricardo may really be said to agree with later writers in finding the maximum limit to wages in the productivity of industry, however much he may differ from them in the narrowness and rigidity with which he may have conceived that limit. It must, of course, be admitted that it would perhaps be more accurate to represent him as limiting profits by wages rather than wages by profits; but the statement in the text may nevertheless be regarded as consistent with the *broad* outlines of his reasoning.

³ I am not sure that we ought not to add ‘with characteristically French exaggeration,’ for M. Leroy-Beaulieu appears in some passages to betray a slight tendency to exaggerate the deficiencies of the older economists.

the extreme point of the maximum limit might be parted, as Roscher has shown, from the extreme point of the minimum, and the causes which might contribute to bring wages further away from the one extreme and nearer the other. He identified, in short, the maximum and the minimum; and this is not misleading when we consider only the question of 'natural,' or, as we should now call them, 'normal' wages. But it is misleading to give so rigid a character as a rapid perusal of Ricardo might easily suggest to this identified maximum and minimum; and, with the exception of some brief passages, he did not examine at all into the causes affecting what we may term 'market wages.'

A later and more comprehensive analysis—assisted in its turn by the altered and altering circumstances of the times—has endeavoured to supply these deficiencies. It has shown how the maximum may be extended as civilisation advances, as invention and knowledge progress, as distribution itself reacts on production by increasing the efficiency of labour, and generally aiding in the augmentation of wealth. It has replaced the suggested rigidity of the Ricardian conceptions by elasticity; and it has also investigated the causes of market wages as distinct from, and yet connected with, normal or natural wages. It has shown how the strength the workmen have gained by the aid of public sympathy and of legal enactment has affected both the market and the normal wages, and has elevated alike what we have called the competitive minimum and the competitive maximum limit. And it has also shown—and this is, perhaps, the most important point for us—how the power of combination has enabled them to raise wages in the market at any particular time from the extreme of the minimum towards the extreme of the maximum. They have become strong sellers, and they have secured the advantage which will always accrue to strong sellers in a market. They have not emancipated themselves from the influence of competition; but they have retarded and modified its action.

In time, no doubt, the influence of competition would effect—as Ricardo, confining his examination almost exclusively to normal wages, held that it did—an identification between the competitive maximum and the competitive minimum limit. But the reflex action of the market wages might cause this identification to be made at a higher or a lower point in the area covered by these two elastic expressions. It might raise the old minimum nearer to a new maximum; it might depress the old maximum nearer to a new minimum. And—as Marx in his discussion of the iron law of wages has shown, although strangely enough he has neglected to draw the natural inference from his argument—it would take time to do this; and during the interval the market influences would bring about many fluctuations in market wages, while the moment the identification had taken place—nay, even while it was going on—new market influences would be at work producing new fluctuations. The identification, then, is theoretical, and refers to normal wages; and the theory of market wages allows us to suppose at any particular time in any particular market an interval between the lowest possible point of the competitive minimum and the highest possible point of the competitive maximum. The minimum, in short, which is to be found, as it was in Ricardo's time, in the cost of production of labour, is an elastic idea, and may cover a wide area; and the maximum, which is also to be found, as it was in Ricardo's time, in the average rate of profits, is also an elastic idea, and may also cover a wide area. There is nothing, then, to prevent

us from supposing that in the labour market at any particular time—and still more so in any particular trade—there may be what we may call a competitive maximum and a competitive minimum limit of wages—the former lying at the point where more wages would mean such a low rate of profit that there would be a pressing danger that the requisite business management and enterprise would fail to appear and the requisite capital cease to be forthcoming, and the latter being found in a similar way at the point where more profits would mean such a low rate of wages that there would be an imminent prospect that labour of the requisite efficiency would not be available. Nor are we debarred from examining the causes which may influence the fluctuation of market wages between these two points, and the market wages, we must remember, will in their turn exercise a reflex influence on normal wages.

Our combination of workmen, then, enjoys the advantages of a strong seller in the market, and within the competitive minimum they may be conceived to have set up, as it were, a minimum limit of their own. Were they not confronted by a rival combination of masters they might conceivably have made this minimum coincide with the competitive maximum. But they are confronted by this combination, which in its turn endeavours to set up, as it were, a maximum limit of its own within the competitive maximum. Were it unopposed it might, in the same way as the combination of the men, effect a coincidence between this maximum and the competitive minimum. But as the case stands neither of the two combinations is unopposed. Neither of the two can secure the terms which it might otherwise have obtained. A compromise is inevitable, and on the one side or the other a greater or less concession must be made. The point at which the agreement is effected will lie between what we have called the competitive minimum and the competitive maximum—understanding by these terms the extreme points of the area covered by the elastic expressions ‘the cost of production of labour’ and ‘the average rate of profits.’ But it will probably coincide with neither of the two; and no theory of pure competition, based as it essentially is on the possibility of infinite subdivision, will enable you to determine at what precise point between these two extreme competitive limits the two combinations, dealing as they are *ex hypothesi* with commodities or services incapable of infinite subdivision, will come to an agreement and effect an exchange. All that you can safely infer is that the point of agreement will not lie outside these limits, unless indeed—though this is not an impossible supposition—either of the two parties is blind to its economic interests.

I have endeavoured to reply to the argument advanced, as I think, erroneously by one of my critics; and I believe that, without undue presumption, I may claim to have answered the other by implication. For while I have tried to show that theoretic economics cannot determine the exact basis of a scale, I have, I think, incidentally indicated the reasons for my opinion that they may have something to say about the general character of that basis. Combinations are, as we have seen, in some degree subject to the influence of competition, which prescribes the extreme limits within which they act; and it is probable, therefore, that economic theory, based as it is on competition, may not be entirely foreign to a treatise on sliding scales, based as they are on combination.

The fundamental principle, indeed, of a scale—the concurrent varia-

tion of wages and prices—is an economic principle; and I do not know myself how it can be satisfactorily or completely investigated without the aid of economic theory. And so, looking at sliding scales, as I have done throughout this paper, as they have been employed in the regulation of wages alone, I have endeavoured to show¹ that the practice hitherto followed in connection with their construction and operation is ‘in a measure in accord’ with the modern economic theory of wages. I do not think, indeed, that it is at present possible to effect a complete reconciliation between the economic theory of wages and the factors entering into the determination of a scale; but I do think that, if we make such allowance for the consequences resulting from the presence of rival combinations as the previous course of the argument has indicated, our emphasis would rather be laid on the points of agreement than on the points of difference.

For there is—and we cannot ignore it—the broad fact of a concurrent variation of wages and prices. That is an element common both to the scale and to the theory. It is true that the prices in the theory are in the present or the future, while the prices in the scale are in the past; that the former are, as I have said elsewhere,² ‘realisable,’ while the latter are realised. But this difference arises from a practical necessity, which may surely be regarded as one of those conditions which generally attach to the putting of theory into practice, but do not on that account make the theory untrue to the practice. You must ascertain the variation that has taken place in prices before you can determine what variation should be made in wages; and your particular practical mechanism for ascertaining prices does not allow you to do so until they have actually been realised. The fundamental principle, then, on which the sliding scale and the theory of wages alike are based, is not affected by this difference; nor is it—if the period of ascertaining the prices be frequent—a difference of any great magnitude. And here it is relevant to add that, in the iron trade at least, the competitive forces on which the theory of wages rests have, as a matter of actual fact, been adduced and accepted as a reason for the more frequent ascertainment of prices.

It is true, again, that the economic theory of wages takes into account the question of the supply of labour and the demand for its services, and that this element is not explicitly recognised in a sliding scale. But here again the difference is in reality less considerable than might be imagined, and is only such as the previous course of the argument in this paper might lead us to expect. The economic theory of wages is based on competition, and the sliding scale on combination. But, as we have already seen, combinations are not entirely emancipated from the influences of competition; and it may fairly be argued that, as a matter of actual fact, competition is implicitly, if it is not explicitly, taken into account in the construction and operation of a scale.

In the construction this is the case, for the basis from which a scale starts is, as Professor Munro has said, ‘historically’ connected³ with competitive influences, so far as they have not been modified by combination. The general basis, again, is only the centre of a number of particular local arrangements, which in their turn start from a time when competitive influences were at work through the medium of combination, pre-

¹ *Industrial Peace*, p. 94.

² *Ibid.*

³ *Sliding Scales in the Coal Industry*, p. 19.

scribing what we have ventured to call a maximum and a minimum limit to wages.

Nor are the facts different from this when we turn our attention to the operation of a scale; for, should particular local circumstances conspicuously alter, the intervention of the joint committee of masters and men might be solicited to alter the particular local arrangements without interference with the average wage which forms the basis of a scale; and should the general circumstances of the trade themselves conspicuously alter, or those of the labour market, experience has shown that the basis originally adopted in the scale may be liable, and that more than once, to readjustment.

Nor must we forget that in some trades—and especially in such trades as the coal and iron mining industries, where the selling price is the sole or paramount consideration—variations in prices may be taken as a tolerably adequate index of the demand and correct price for labour in those particular trades. And this is likely to be the case in a still higher degree, on account of the fact that the combinations present material hindrances to the entrance of outside competitors into the market, and thus the supply side of the question is in a large degree robbed of its importance and the supply becomes stereotyped.

Where, indeed, the cost of the raw material is an appreciable and fluctuating element, the index afforded by variations in prices becomes deficient. But here I can only remark that the inclusion of changes in the cost of the raw materials among the various factors entering into the determination of a scale may be a matter of time, and may introduce an added complexity, but is certainly in no way incompatible with its essential characteristics. We are indeed only too liable to forget, on the one hand, that sliding scales possess considerable elasticity, so much so that their complete reconciliation with economic theory, *if we allow for the presence of the combinations on which they rest in industrial matters*, is at least conceivable; and on the other that they are as yet in their infancy, and may develop in a manner and degree that it would be folly to attempt to anticipate. They may possibly be reconciled with more completeness to economic theory, and they may also help to modify that theory. There is no doubt that they do present the spectacle of two combinations expressly recognising, and endeavouring to facilitate in its operation, a fundamental principle of competitive economics—the concurrent variation of wages and prices; and there is also no doubt that where you have a scale regulating wages there you have two combinations influencing the conditions of the competitive market in such a way that no theory of pure competition will enable you to determine the exact point at which they will agree on a price. The starting-point then of a scale is arbitrary; its general working is the exemplification of an economic principle.

And it is, we must not forget, a principle of great importance. To satisfy, indeed, all the conditions that economic strictness would require, it ought, perhaps, to be elaborated in some such way as Professor Marshall has pointed out.¹ But, presented as it is in its broad and, if you like, unscientific form, had it met with general recognition I think that it is scarcely too great presumption to infer that no Royal Commission would be sitting at present to investigate the 'recent changes in the

¹ *Industrial Peace*, Preface, pp. xx.–xxii.

relative values of the precious metals; that the adjustment of wages to lower gold prices would have taken place automatically, and that we should not now be hearing of supposed or real bounties to Indian spinners and manufacturers of cotton and growers and sellers of wheat.

And this leads me to consider one general point in conclusion. The sliding scale is indeed in its infancy, and only affects a minority of workmen. It has been applied with success to those industries alone where it can be applied with the least complexity; and the fact that it has not been recognised, save in a very partial manner, in the cotton trade—and yet the regulation of wages by lists in that trade is, as any student of the exhaustive report submitted to this Section last year will admit, by no means free from complexity—ought to render us very chary in venturing upon any rash prophecy of its more extended adoption. It may, however, and I think that it will, be extended in the future; but, even as it is, it may perhaps be regarded as significant of wider and more important changes. It is based, as we have seen, on combinations, and the action of combinations, as we have also seen, undoubtedly exercises an influence on the competitive market. Is it then quite fanciful to regard the adoption of the sliding scale as part of a growing collectivist tendency in economic society?

And here we must be careful to avoid over- and under-statement alike. We must remember, on the one hand, how large is the sphere occupied by competition in the construction and the operation of a scale; and, on the other, we must not minimise the significance of the fact that two powerful combinations meet one another and agree on a joint policy. I am not one of those who think that society will ever be organised on one comprehensive plan. I do not believe in the dull and stagnant uniformity of one unvarying method of production universally prevalent. As in the past so in the future there will, I think, be almost multitudinous variety. But I do believe that there is more than one sign—and that among these we may include the regulation of wages by sliding scales—that the extreme individualism which has been attributed, not without exaggeration, to the economic organisation of the early part of this century is giving way, here a little and there a little, to collectivist influences. I do believe that methods of collective action, be it that of the State, be it that of private corporations and associations and combinations, may occupy a larger and a more explicitly recognised place in the future economy of society than they have done in the immediate past.

I am not afraid of this tendency, because I think that its enemies and its advocates alike have exaggerated its proportions and projects. It will not, I believe, any more than the sliding scale has done, emancipate itself from competition, but it will utilise and modify it. It will not, any more than the sliding scale, overthrow economic theory, but it may supplement it and correct it; and economists, whether historical or deductive, will, I believe, devote as much and as fruitful patience and acumen to the study and analysis of society as it is influenced perhaps in a larger degree by this collectivist tendency, as they have done to society as it was influenced perhaps in a larger degree by the individualist tendency. They will be ready to correct their theory by the study of facts, and to assist their study of facts by the help of theory, as the best representatives of either school have done, if not explicitly, at least implicitly, in the past.

Index-numbers as illustrating the Progressive Exports of British Produce and Manufactures. By STEPHEN BOURNE, F.S.S.

[A communication ordered by the General Committee to be printed *in extenso* among the Reports.]

A PAPER read at the Aberdeen Meeting of 1885 endeavoured to show the 'Use of Index-numbers in the Investigation of Trade Statistics,' and set forth in several forms the comparisons which might thus be made between the exports of 1883 and previous years. The publications of the Board of Trade since that date enable similar calculations to be made for the four later years, and it is thought that these figures may be interesting as an addendum to those then produced. The materials then used were wholly drawn from the official tables and did not extend to the imports, which are generally susceptible of being so treated; nor does the present inquiry travel beyond the range of that paper.

The method then adopted was to fix upon 1,000, 100, 10, or 1, as the index for 240,000,000*l.*, the whole value of the British exports of 1883, and to split this up into so many numbers as there were specified articles the values of which made up this sum of 240,000,000*l.* Thus cotton yarn, having been exported to the value of 13,500,000*l.*, had for its index-number 56; and in like manner every other article comprised in the total of 1,000. Such a set of figures if prepared for other years—that is, taking 1,000 to represent 240 millions of money—would show at a glance the progress of the export trade for any number of years either backwards or forwards for which the requisite data were available.

But value alone is no evidence of the extent of our trade, since prices differ greatly in one year from others; and hence the volume of such exports can only be brought into the requisite proportion to the whole of its own or other years, by reducing the weights and measurements to a common standard or properly altering the index-number.

This is done by considering the price of each article in 1883 to be the unit 1*l.*, and that for other years to be more or less than this by the proportion in which it differs. Thus cotton yarn in that year was 12·25*d.* per pound, that for 1887 10·88*d.*, and reckoning the former to be 1*l.*, the latter is between ·89 and ·90. Now if we wish to convert the value of the 1887 export, viz., 11,400,000*l.*, the index-number for which is 47, into the equivalent in volume which at the price of 1883 the value of 1887 would have procured, we divide 47 by ·89 to find 53 as its index to compare with that of the former year.

Pursuing a similar course for all the articles of which the quantities and the prices are specified in the accounts, and assuming that those for which these particulars are not attainable should be in the same ratio as those which are so distinguished, we get an index-number for the whole which represents the difference in the extent of our trade as regards quantity. With these materials it can also be shown at a glance wherein the several articles and the several years correspond to or differ from each other.

The first of the following tables sets forth in detail the method of comparison between 1883 and 1887. The second condenses the figures of the five years into the index-numbers for classes of goods; and the corresponding indices calculated at the prices of 1887.

A. British Goods exported in 1887 compared with those of 1883.

Although the object of this paper is rather to show the plan adopted and to add to the details of the former paper those relating to subsequent years; it would lack the interest to which the subject, if not the method, is entitled, were there to be no allusion to the results at which we are thus enabled to arrive. Comparing then the figures of the year last ended with those of 1883, which has been adopted as a standard, we find that, starting with 1,000 as the index-number to represent the total exports of the former year, 922 will be that for 1887, because the export of that year fell short of those in 1883 by 7·8 per cent.; but that having regard to the quantities of the several articles exported during last year and the higher prices which prevailed in 1883, we must make additions to most of them, which will bring the index up to 1,062, and, therefore, that instead of the volume of trade having diminished in the proportion which the value taken alone would indicate, it has increased by 6·2 per cent. beyond that of 1883. In fact, that had the goods we thus sold in 1887 been parted with in 1883 they would have realised 253,000,000*l.* instead of but 221,000,000*l.*; in other words, that our trade in this particular branch has been larger by $\frac{42,000,000*l.*}{221}$, or 19 per cent., more than it appears to be, if we take value alone as our guide.

Treating the intermediate years in the same way, 1886 is increased by $\frac{28}{212}$, or 13·2 per cent.; 1885, $\frac{19}{213}$, or 9 per cent.; and 1884 $\frac{9·5}{233}$, or 4·1 per cent., the actual index-numbers for the values from 1883 being in the series of

$$1,000 : 971 : 888 : 885 : 922 ;$$

those for volume :

$$1,000 : 1,010 : 967 : 1,002 : 1,062 ;$$

and carrying the comparison further back it was shown in the Aberdeen Paper that, whilst the value series for the years 1883, 1879, 1875, 1873, and 1865 were 1,000 : 798 : 931 : 1,063 : 695, those for volume were 1,000 : 798 : 739 : 727 : 460; thus giving an accurate gauge of the conditions as to total volume as well as to total value for the four years since 1883 and four selected ones between that year and 1865. The same comparison may be made at sight with any single article either in relation to itself for previous years or as to its relative importance to others in one or many years.

Looking down the list of articles enumerated in the published accounts it may be seen how much of our manufacturing power expended upon the production of goods for export is so spent upon each one, and wherein the variations in the volume as contrasted with the value have consisted. Grouping together all the textiles and all the metals and throwing all the others into a third, we learn that the value of textiles is represented by the index 410, the volume by 463, a difference of 12·4 per cent.; that of metals

and minerals, including of course coal, the indices are 165 and 206, a difference of 23·1 per cent.; whilst the whole stands at 922 and 1,062, or 10·85 per cent., thus showing the relative proportions of the two most important branches of our national industries, and the degrees in which they have varied in the one year from the other. It must be remembered always, however, that a vast variety of articles into which the materials are converted when finished, as, for instance, apparel from cotton and hardware from iron, are included in the unenumerated because we have no facts as to the alterations either of quantity or price.

Another branch of the inquiry, even as regards the export trade, would require similar figures and calculations for the imports of the raw materials in which we work. These are widely different in the case of the two principal branches, for almost all of those enumerated with textiles are of foreign production, whilst those employed in the metal industries are chiefly from native sources. To select for illustration the one class of cotton goods, of which the chief constituent is of foreign growth. Cottons altogether have an index-number of 278 out of 922 for value, and one of 318 out of 1,062 for volume. The imports of cotton wool (after deducting the quantity sent away again in its original condition) are indicated by 143 for value and 166 for volume, which are very nearly one-half of the whole export figures. The index for prices is almost exactly the same, namely, ·86 or ·87, showing that there must have been a fall in the labour or other elements of the cost of production in the same ratio as in that of the raw material.

These particulars are not singled out as proofs of the progress the country has been making—for that would require a much more detailed examination—but as instances in which the method of reduction into index-numbers facilitates inquiry and exemplifies its results. For whilst as regards each individual article or material its own figures furnish the best means of comparison, it is only, as is well known to all inquirers, by getting some common basis that we can effect the necessary additions, deductions, or combinations without which it is not possible that the whole should be shown or general conclusions established.

The Friction of Metal Coils.

By PROFESSOR HELE SHAW *and* EDWARD SHAW.

[A communication ordered by the General Committee to be printed *in extenso* among the Reports.]

COIL friction has long been used as a powerful means of communicating or retarding motion. Even where only a partial coil is employed, as in the case of leather or rope belting and flexible metal brake bands, the frictional resistance to be obtained by small pressures is very considerable; but where several complete convolutions are used, the effects to be produced are unlimited. Thus a rope, half a turn of which is taken round a post, will enable a man at one end to sustain a force three times as great at the other; but the resistance is multiplied three times for each half-turn, so that in four or five turns a resistance of several hundred tons might be obtained, and the result only limited by the ultimate tenacity of the rope. On first thoughts, it would not be obvious that,

with the exception of flexible metal bands and wire rope, metal could be employed in coil friction. In exactly similar circumstances this certainly could not be done; but suppose the conditions to be altered, and the metal coil to be only used under circumstances which do not require it to be unwound, as is done with rope, then the properties of coil friction may also be taken advantage of if the coil is sufficiently flexible for the purpose. It is true that metal is inferior in frictional resistance to rope, but this advantage may easily be obviated by using a greater number of coils, whereas the much higher tensional strength and durability of metal point to many valuable applications. The chief applications, which have been made with more or less success, have been in connection with clutches and brakes, and the principle of operation is very simple. The metal coil is either wound round a shaft or the sleeve of a pulley, or else it is contained within a cylinder attached to either. One end, which will always be referred to in the present paper as the 'tail,' is by some means or other brought into frictional contact with the shaft, sleeve, or cylinder, and is thus carried round if the surface be in motion, or retarded if the coil itself be in motion and the surface at rest. The attachment of the 'head' of the coil prevents its following the tail until a considerable tension is put upon the whole coil. Thus, if the coil encloses the shaft or sleeve, it is made to wind up upon the shaft, becoming of less internal diameter and taking a frictional grip throughout its whole length; but if, on the contrary, it is enclosed in a cylinder, it is made to unwind, and so expand. In either case the result is the same, and a force of any required magnitude may be transmitted by this means. In order to illustrate this action, a piece of apparatus has been devised by the authors which may interest those who have never seen any example of the power of metal coil friction. A weight of 56 lbs. is raised by a drum and handle. The shaft—1 in. in diameter—to which the drum is attached, passes through its bearing in the frame, and is attached to the head of a metal coil of iron wire $\frac{1}{8}$ in. in diameter. The coil encloses a sleeve carried by the frame, and the tail of the coil is free. As long as this is the case the whole weight of the 56 lbs. has to be sustained by means of the handle; but if a weight of 10 oz. is now suspended to the tail, a grip is obtained throughout the coil, by means of which the weight is sustained, which from the difference of leverage is equivalent to a force at the head of the coil of 200 lbs. The load has in this way been increased at a previous trial until the head of the coil was torn off without adding to the weight at the tail. If the small weight is raised, the load falls; but its fall is instantly checked by releasing the small weight again. To show the effect of the number of convolutions various coils are substituted, and it is seen that when there are only four coils instead of eight, an increased weight, many times as great, is required to sustain the load. The effect of simply twisting the tail of the coil is very remarkable, as may be ascertained by means of the small wire coils now passed around the room. In this case it is not necessary to hang any weight at all upon the tail itself; and the self-sustaining action of the coil, which permits perfectly unconstrained motion in one direction but instantly checks any motion in the other, is very striking.* This effect is still more strikingly exhibited by means of the experimental apparatus. The tail of the small coil is twisted so as to just touch the shaft with a slight pressure. The load is then raised, and no resistance whatever is felt from the coil as long as the handle is being turned in the correspond-

ing direction; but immediately the handle is released and the weight tends to fall, the coil comes into operation, and grips the shaft with a force which not only prevents the weight from falling, but also resists the further load now applied, the two being together equivalent to a total pull of nearly 1,000 lbs. upon the coil. The important applications of this kind of action in self-sustaining hoists, silent feed motions, and for other purposes, are obvious.

Coming to the applications of metal coil friction which have been proposed, we find that in 1877 Mr. Rider, an American, devised the friction clutch shown in Fig. 1. In this clutch a cone sleeve, A, is moved

by means of a lever acting at B, and so throws open a split cone lever, C, and wedges out the tail of the coil against the cylinder in which it is enclosed. The coil, which is revolving, is thus unwound, and so presses upon the inner surface of the cylinder, which it carries round, and with it the pulley to which it is attached. Fig. 2 shows an application of the converse and most usual case, in which the coil winds up and closes upon a shaft or sleeve which it surrounds. This friction clutch was invented by Mr. Sterling in 1882, and its action is easily understood. A sleeve, A, carries along one end of a toggle joint B, and so pushes out the end of the lever C, and thus presses the tail end of the coil. The coil consequently tightens upon the boss of the pulley D, and carries it round. There is also an example of wire rope coil friction shown at E, Fig. 2. An arrangement has been recently devised by M. Gambaro, a French engineer, and applied as a brake to a crab winch. The same inventor has proposed a system of continuous railway brakes on this principle. Professor Osborne Reynolds has also applied metal coil friction in an ingenious arrangement for turning the valve rods of the experimental steam engine at Owens College, thus enabling the governor to be the means of almost instantly altering the position of the slides, thus regu-

lating the admission of steam. Those who have seen this arrangement at work must have been struck by the suddenness and force with which the coil comes into action. Notwithstanding these and other applications of coil friction, the actual amount of knowledge on the subject, at any rate in a published form, is very small, and the accepted theory of

ordinary coil friction, which takes no account of the comparative rigidity of the coil, is not directly applicable in the case under discussion. Mr. Edward Shaw, in attempting to make use of metal coils, found various practical difficulties and apparently anomalous results, which led the authors to think it worth while to make some experiments bearing upon certain features in the application of this form of coil friction.

Form of coil.—The first points to be considered are those of the requisite form and dimensions of coil; for it is obvious that while sufficient strength is required at the head of the coil to resist a considerable force, the tail need not be of similar section. It is not merely waste of metal to have the section uniform, but the want of flexibility thus entailed seriously impairs the efficiency of the coil. Fig. 3 will illustrate this point, in which *a* shows the section of a coil which has been adopted by one or two inventors, whilst *b* is a section of the coil reduced in thickness, but of uniform width. This has the disadvantage of being too broad at the tail, and the quantity of lubricant getting under such a surface prevents the initial grip taking place so readily. Fig. 3 *c* shows a very efficient form in which the advantage of smaller space (the number of convolutions being the same as in *b*) and more sudden initial grip are insured. A very good form of coil is that shown in *d*, in which the last coil or two are circular in section. M. Gambaro and Professor Reynolds have both employed coils of decreasing width and thickness. With regard to the diameter of the coil, this, where perfect flexibility is assumed, is a matter of no importance, except as regards the obvious effect upon the leverage at which the resistance acts. With metal coils the case is different, as the larger the diameter the more readily the surface comes to its bearing for a given cross section, and with a given initial clearance the comparative distortion is less the greater the radius of curvature. In order to have the internal surface of true cylindrical form, several coils were

rigidly held and bored out, some even being afterwards scraped to a bearing. It was, however, found that there was no necessity for such refinement, as after a very brief period coils simply made by twisting a

taper rod round a turned cylinder found their own bearing, and were quite as effective as those which had been bored out.

Relation between force and resistance.—Of the coils exhibited, those lettered *a*, *b*, *c*, and *d* had sections corresponding to those similarly lettered in Fig. 3. These four coils have been experimented upon by means of the apparatus shown in Fig. 4. On the face-plate of a lathe were fixed cylinders upon which the coils fitting loosely were successively

placed. The head *h* of the coil *C* was prevented from revolving by means of a lever *L* having a fulcrum at *F* attached to the lathe bed *B*. The lever *L* is counterweighted by means of a scale-pan *W* hanging over a

pulley M, and the loads which are placed in the larger scale-pan W thus have an effect just twenty times as great upon the head of the coil. The tail of the coil *t* was attached to a delicate spring balance, S, which in turn was suspended by a cord passing over pulleys, N N. By exerting a greater or less force on this cord any required tangential pressure could be brought to bear upon the tail.

(a) Coil *a* consists of seven convolutions of $\frac{1}{2}$ in. square cast steel, and therefore not being very flexible, was made a good fit upon the cylinder; but notwithstanding this a pull of no less than 25 pounds was required to raise the weight of the lever, which was equivalent to a force of 140 pounds at the head of the coil. The result of increasing the pull on the tail is shown below:—

F	.	.	25	37	41	43	47	51	55	59	63	67	70
R	.	.	140	240	260	300	310	350	410	480	520	660	700

F = force on tail in pounds. R = resistance on head in pounds.

These results, which are not very uniform, and point to the evil of using rigid coils, were obtained with dry surfaces. The effect of lubricating the surfaces always appeared to be the reverse of what might be expected; thus, in the present case, a pull of only 32 lbs. instead of 37 lbs. was sufficient when lubricant was freely applied to overcome a load of 240 lbs., 37 lbs. replacing 55 lbs. and balancing 410 lbs., 49 lbs. replacing 70 lbs. and balancing 700 lbs.

(b) Coil *b* of wrought iron, consisting of eight convolutions of $\frac{1}{2}$ in. \times $\frac{3}{8}$ in. tapering to $\frac{1}{4}$ in. \times $\frac{1}{8}$ in. required only a force of 3 lbs. to make it lift the lever; but having once done this, the grip upon the surface was absolute, and apparently sufficient to raise the maximum pull that could safely be applied, which was 4,000 lbs. The only effect of lubrication was to make the gripping action more sudden and violent.

(c) Coil *c* of steel, consisting of eight convolutions tapering from $\frac{3}{4}$ in. square to $\frac{3}{8}$ in. square section, gave the following uniform series of results:—

F	.	.	4 $\frac{1}{2}$	5	5 $\frac{1}{2}$	6	6 $\frac{1}{2}$	7	7 $\frac{1}{2}$	8	8 $\frac{1}{2}$	9	9 $\frac{1}{2}$	10
R	.	.	140	220	300	380	460	540	620	700	780	860	940	1020

F and R having the same values as before.

When the lubricant was used, the results, though not quite so uniform, did not differ greatly from the above, but were again slightly less, showing that lubrication makes the action more effective.

(d) Coil *d*, consisting of ten convolutions of $\frac{3}{8}$ in. square wrought iron, tapering to $\frac{3}{16}$ in. round steel, behaved exactly in the same way as coil *b*, but the effect was more marked, and 1 lb. on the tail resulted in an absolute and complete grip of the whole coil.

Influence of velocity.—The effect of change of velocity of the moving surfaces was very surprising, the general result of decrease of velocity being to enable a small force on the tail to put the coil into operation. This was not merely the case when the coil was revolving and the result of centrifugal force acting to keep the coil from contact, but was just as marked when the shaft or sleeve rotated and the coil remained at rest. Again, the chief effect of change of velocity seemed to be felt with coils similar to *a* and *b* on the diagram, in which the broad surfaces seem to hold the lubricant more than the narrow ones. In experimenting upon coil *c* it was found that with a surface velocity of 15 ft. a minute 3 $\frac{1}{2}$ lbs. at

the tail produced a force of 140 lbs. at the head, whereas at 180 ft. per minute $5\frac{1}{2}$ lbs. was required to obtain the same result. With a very short coil of section *c*, having only five convolutions, the sleeve inside the coil could be rapidly revolved, with no apparent resistance; but directly the speed was reduced below a certain limit, the coil gripped with its full force. It may be that further experiments in this direction will throw some light on frictional resistance at high velocities.

The foregoing results, which are a brief *résumé* of the experiments upon the four typical coils, at first appear to be contradictory. Two of the coils behave in a very different manner to the other two. Thus, with *a* and *c*, after allowing for the stiffness of the spring, the experiments agree with the usual theory, which assumes that the forces at the two ends of the coil are directly proportional to each other when the arc of contact and coefficient of friction are constant, as was the case in the experiment. This is not so evident with the former of the two, in which the stiffness of the coil and the manner in which it acted prevented very accurate results being obtained. With the latter it is easy to see that an equation of the form

$$F = k R + m$$

represents the results, *F* being the force on the tail, *R* being the resistance on the head, while *k* and *m* are constants. The exact value of *m* is 3.625, this being a measure in lbs. of the stiffness of the spring, since when the resistance is zero, *m* is equal to the force on the tail in lbs., and it will be seen that for each increase of $\frac{1}{3}$ lb. on the tail there must be an increased resistance of 80 lb. on the head. With the coils *b* and *d* there is no such proportion between the two effects, but when once the coil comes into operation the grip is sudden and absolute. The explanation is found by reference to the dimensions of the coils themselves, when it will be seen that the section towards the tail in the case of *b* and *d* is much less than that in the case of *a* and *c*; thus, when the initial resistance in the latter case to closing the coil due to its stiffness is overcome, the bearing is continuous, and the force then on the tail is probably far in excess of that which would be required to even tear off the head of the coil. It will thus be evident that on attempting to make use of metal coils for practical purposes two distinct modes of operation are available, which, although so very different, can be obtained by merely varying the relation between the number of convolutions and cross section of the coil. Where a definite ratio is required between force and resistance, then the number of coils must be reduced or the cross section towards the tail increased; but if small constant force only is available to put into operation, whatever be the resistance at the head, then the convolutions must be sufficiently numerous and the tail end of the coil sufficiently flexible. The objection to the former is that any variation in the coefficient of friction makes a considerable difference in the result; but in the latter case, where the force required to start the coil is so extremely small, some effective means of releasing the grip when it reaches a certain definite amount would enable such coils to be effectively applied for purposes such as clutches and brakes.

NOTE.—In the discussion which followed the reading of the paper, various suggestions were made to account for the peculiar effect of the lubricant in increasing the effective action of the coil. The authors, upon further consideration, believe the true reason to be as follows. At times,

when running dry, it was noticed that the application of the load produced a vibratory effect, which was sometimes so great as to make itself evident by auditory means. This vibration in all probability always existed, to a greater or less extent, throughout the experiments as long as no lubricant was used, and would be quite enough to account for the diminished power of the coil considering the great resistance it had to overcome, and would explain the more effective action resulting from the application of the lubricant, which no doubt prevented such vibration taking place. Certainly no vibration caused by alternate gripping and release of the tail of the coil was ever noticed when lubricant was being used between the surfaces in contact.

Sur l'application de l'analyse spectrale à la mécanique moléculaire et sur les spectres de l'oxygène. Par Dr. J. JANSSEN.

[A communication ordered by the General Committee to be printed *in extenso* among the Reports.]

L'ANALYSE spectrale constitue l'une des méthodes les plus fécondes d'investigation dont le physicien puisse disposer pour l'étude de la constitution des corps, soit au point de vue chimique, soit au point de vue de la mécanique moléculaire.

Jusqu'ici l'analyse spectrale a été principalement appliquée à la détermination de l'espèce chimique.

Nous nous proposons de montrer dans ce travail qu'elle est non moins féconde pour l'étude des questions de mécanique moléculaire.

Les études suivantes sur les spectres de l'oxygène dans leurs rapports avec les densités de ce gaz sont un essai tenté dans cette direction.

1. *Laboratoire et instruments d'expérience.*—La disposition du lieu et des bâtiments à l'observatoire de Meudon a permis la création d'un laboratoire qui a environ 100 mètres de long et contient tous les instruments nécessaires pour l'étude des gaz sous de grandes épaisseurs et de hautes pressions et notamment :

Un tube en fer et deux en acier doublé de cuivre rouge, ayant 60 mètres de long et pouvant supporter une pression de 200 atmosphères.

De nombreux tubes de longueurs et de diamètres variés permettant d'étudier les gaz sous des pressions qui dans des cas spéciaux peuvent aller au delà de 1,500 atmosphères.

Il y a lieu de signaler une balance pouvant peser 40 kilogrammes à un centigramme près. Cette balance permet de déterminer la densité d'un gaz indépendamment des pressions et par la seule considération des poids. Le tube, contenant le gaz sous pression, est équilibré sur la balance. On fait sortir le gaz, on rétablit l'équilibre par des poids marqués, ce qui fait connaître le poids du gaz sorti, et ce poids combiné avec la capacité du tube préalablement déterminée (après les corrections nécessaires) permet de conclure la densité.

Les sources de lumière employées dans le laboratoire sont la lumière de Drummond, la lumière électrique, la lumière solaire.

2. *Spectres de l'oxygène.*—Ces études devaient commencer par l'oxygène. Ce gaz, en effet, par les phénomènes de modifications moléculaires qu'il présente, notamment celle qui donne lieu à l'ozone, paraissait être le

gaz qui promettait les résultats les plus intéressants pour une étude de structure moléculaire par l'analyse spectrale.

Au moment où j'ai commencé ces études en 1885 M. Egoroff était occupé à vérifier si les groupes A et B du spectre solaire appartenaient effectivement, comme il l'avait soupçonné, au gaz oxygène.

Malgré les facilités que me donnaient les moyens puissants dont je disposais, j'ai tenu à lui laisser poursuivre cette étude commencée, estimant qu'on n'a pas le droit de toucher à un sujet abordé par un auteur tant que cet auteur manifeste l'intention de poursuivre ses études. Ces habitudes de délicatesse scientifique ne sont pas malheureusement assez suivies.

Les premières études sur le gaz oxygène ont été faites avec le tube en fer de 60 mètres, fermé à ses extrémités par des glaces doublées. La lumière employée fut la lumière de Drummond (becs multiples disposés en ligne verticale). Le faisceau est rendu parallèle avant son entrée dans le tube et à sa sortie il est concentré sur la fente du spectroscopie.

Variation apparente des spectres avec la pression.

Le groupe B du spectre solaire commence à être nettement perceptible avec 2 atmosphères d'oxygène. Le groupe A commence à l'être beaucoup plus tôt.

Ces groupes se développent naturellement en intensité avec l'augmentation de pression.

Bandes obscures.—Mais de 6 à 12 atmosphères on voit apparaître un phénomène spectral nouveau : ce sont des bandes obscures estompées, paraissant très difficilement résolubles.

La première se montre près de D du côté du violet.

Une seconde entre C et D.

Une troisième près de F du côté du violet.

On peut en développer d'autres par l'augmentation de pression, mais nous considérerons seulement ces trois bandes d'absorption pour le moment. Voici la position de ces bandes (il faut remarquer qu'elles augmentent de largeur et d'intensité avec la pression et l'épaisseur de gaz traversé, suivant la loi générale de ces phénomènes).

Bande du rouge, $0^{\mu}632$ à $0^{\mu}622$.

Bande du jaune près de D, $0^{\mu}580$ à $0^{\mu}572$.

Bande du bleu près de F, $0^{\mu}482$ à $0^{\mu}478$.

Il paraissait d'abord singulier qu'un gaz donnât naissance à des bandes paraissant très-semblables à celles que donnent les corps solides ou liquides, et en outre, que ces bandes fussent associées, dans le même corps, à un autre système de raies, comme B, A ; aussi ces bandes singulières ont-elles attiré notre attention tout d'abord, et avons-nous cherché à faire une étude approfondie de la question de principe qu'elles soulevaient.

Il fallait avant tout démontrer qu'elles appartenaient bien au gaz oxygène, et qu'elles n'étaient point dues à la présence de vapeurs ou gaz étrangers, produits soit dans la préparation de l'oxygène, soit dans les opérations qui ont pour but de le comprimer. Nous avons alors préparé l'oxygène par des moyens variés : par le chlorate de potasse, en purifiant et desséchant avec soin le gaz produit ; par l'oxyde de mercure ; par l'eau oxygénée, etc. Les bandes ont toujours persisté. Nous avons ensuite institué une expérience propre à montrer la non-intervention des carbures d'hydrogène dans la production du phénomène.

Le gaz oxygène, au sortir de la pompe, et avant son entrée dans le tube en expérience, était forcé de passer dans une couronne formée par

un tube capillaire de cuivre rouge, couronne qui était portée à la température du rouge vif.

Dans ces conditions l'oxygène subissait l'action d'une très haute température capable de décomposer complètement les carbures d'hydrogène qu'il eût pu contenir. Or, les bandes ont encore fait leur apparition aux mêmes pressions.

Nous avons encore voulu nous démontrer par une expérience directe que l'action des pompes n'intervient pas dans la production des bandes.

Aux deux extrémités du tube de 60 mètres on a branché des tubes flexibles mettant ces extrémités en communication, au moyen de robinets, avec la pompe foulante.

Ces dispositions prises, on a foulé dans le tube 6 atmosphères d'oxygène de manière que la bande de D fut aussi faible que possible quoique encore perceptible.

La pompe alors fut mise en action ; elle prenait le gaz à une extrémité du tube pour le faire rentrer par l'autre extrémité.

Dans cette opération la pression dans le tube de 60 mètres n'augmentait pas, puisque ce tube empruntait à lui-même le gaz que la pompe lui envoyait ; les bandes ne pouvaient donc pas augmenter en intensité du fait de l'augmentation de la pression.

Mais si l'action de la pompe eût été capable d'intervenir dans la production des bandes, l'expérience l'eût mise infailliblement en évidence, puisque cette action pouvait être continuée aussi longtemps qu'on voulait. Or, après six heures d'action de la pompe, les bandes présentaient le même aspect qu'au début de l'expérience.

Les bandes sont donc indépendantes de l'action des pompes.

En résumé :

Les bandes persistent quelle que soit la provenance de l'oxygène employé. Elles ne peuvent être attribuées ni à la présence de carbures d'hydrogène qui auraient échappé aux moyens de purification du gaz, ni à une action inconnue mais possible de la pompe.

Les motifs pour les attribuer à l'action de l'oxygène prenaient donc déjà une grande force. Cependant, comme l'oxygène fait partie de l'atmosphère terrestre, on devait, avant de considérer la question comme résolue, examiner les circonstances de la production des bandes dans leurs rapports avec l'atmosphère.

Or, de ce côté, surgissait une grande difficulté.

En effet, l'oxygène contenu dans l'atmosphère terrestre, représentant environ la cinquième partie du poids de cette atmosphère, équivaut à une couche gazeuse de 1,500 mètres environ de hauteur à la pression d'une atmosphère ou de 250 mètres à 6 atmosphères.

L'action de l'atmosphère, d'après ces données, devrait donc être plus que quadruple de celle du tube de 60 mètres.

Comment se fait-il que le spectre solaire aux environs de midi et même quand le soleil est assez loin du méridien ne présente aucune des bandes en question ?

Cette considération ne laissait que deux alternatives : ou d'admettre que l'action qui produisait les bandes suivait une loi différente de celle acceptée jusqu'ici, c'est-à-dire, celle de la proportionnalité au produit de l'épaisseur gazeuse traversée par la densité du gaz, ou bien que des gaz étrangers et actifs n'avaient pas été éliminés.

Les précautions prises pour écarter toute action possible des corps étrangers m'ont paru assez complètes pour chercher ailleurs la cause du phénomène.

J'ai alors varié mes expériences avec des tubes de longueurs différentes, chargés de gaz à des pressions variables.

Ces expériences m'ont conduit en effet à soupçonner une influence particulière de la pression et par suite de la densité sur la production du phénomène.

Pour mettre nettement en évidence cette influence de la densité, j'ai institué l'expérience suivante. A côté du tube de 60 mètres a été placé un tube de 20 mètres de même diamètre et pouvant être mis en rapport avec lui par des prismes à réflexion totale.

La lumière de la source traversait le tube de 60 mètres, se réfléchissait deux fois, pénétrait alors dans celui de 20 mètres et était analysée à la sortie de celui-ci.

Les choses ainsi disposées, on fit le vide dans le tube de 60 mètres et on foula au contraire de l'oxygène dans celui de 20 jusqu'à ce que les bandes commençassent à se montrer. Il a fallu pour cela 12 atmosphères. Ceci fait, on ouvrit le robinet de communication entre les deux tubes. L'oxygène se répandit dans le tube de 60 mètres et se partagea entre les deux tubes. La pression tomba à 3 atmosphères et les bandes disparurent complètement.

Cette expérience mettait nettement en évidence l'influence de la densité. En effet, dans la seconde phase de l'expérience le faisceau lumineux avait traversé une quantité de matière gazeuse équivalente à celle de la première phase, puisque, si la densité était devenue quatre fois plus faible, l'épaisseur gazeuse était quatre fois plus grande. La disparition des bandes ne pouvait donc être attribuée qu'à l'abaissement de la pression, qui n'était pas compensée par une augmentation proportionnelle de l'épaisseur gazeuse traversée.

Cette influence particulière de la densité nettement mise en évidence, il restait à trouver la loi suivant laquelle elle agissait.

On institua alors une série d'expériences dans lesquelles on fit varier tout à la fois la longueur des tubes et la pression du gaz. Mais pour donner une base précise à ces expériences on adopta comme point où la force d'absorption est toujours la même le moment où une bande est naissante, c'est-à-dire, commence à être perceptible lorsque le spectre est en mouvement.

Ce moment de la naissance d'une bande n'est évidemment qu'un phénomène relatif qui dépend de l'intensité lumineuse, de la sensibilité de l'œil, etc. On s'est attaché à conserver ces conditions sensiblement les mêmes dans les expériences.

Ceci posé, voici un premier tableau où sont résumés les expériences sur l'apparition de la bande près de D quand la longueur des tubes varie :—

Longueur des tubes	Pression sous laquelle la bande est naissante	Pression calculée d'après le produit de l'épaisseur par la densité ϵd
metres	atm.	
60	6	6
20	10-12	18
5	23	72
1.47	38	240
0.75	50-55	480
0.42	70-75	858

La première colonne contient les longueurs des tubes contenant l'oxygène, la deuxième les pressions sous lesquelles la bande près de D est naissante. La troisième contient les pressions qui eussent dû être observées si la loi du produit de l'épaisseur gazeuse par la densité régissait le phénomène.

On voit que l'écart entre les nombres de cette troisième colonne et ceux de la seconde se prononce dès les premières expériences et que quand la longueur du tube tombe au-dessous d'un mètre il est énorme.

La loi du produit de l'épaisseur par la densité ou par la première puissance de la densité est donc insoutenable.

On voit de suite que ce doit être une puissance n de la densité supérieure à la première qui doit permettre de représenter le phénomène.

Soit donc F la force en question, δ la densité du gaz et e l'épaisseur gazeuse traversée; on aura $F=e\delta^n$. Et pour deux expériences dans lesquelles les épaisseurs seront e' et e'' et les densités δ' et δ'' on aura $e'\delta'^n=e''\delta''^n$.

Pour obtenir la valeur de n prenons les logarithmes :

$$\log e' + n \log \delta' = \log e'' + n \log \delta'' ;$$
$$\text{d'où } n = \frac{\log e'' - \log e'}{\log \delta' - \log \delta''}.$$

Il faut maintenant substituer dans cette équation les valeurs de e' , e'' , δ' , δ'' pour deux expériences bien choisies.

Nous prendrons celles qui se rapportent aux termes extrêmes de notre série, ce qui donne plus de chances d'exactitude; ce sont les expériences avec le tube de 60 mètres et celui de 0^m.42.

On a alors :

$$n = \frac{\log 60 - \log 0.42}{\log 72 - \log 6} = \frac{2.1549020}{1.0731070} = 2.008.$$

Ainsi $n=2$.

Il est même bien remarquable que cette valeur se trouve déterminée avec une précision aussi considérable.

Pour démontrer que cette valeur de n est bien celle qui répond à l'expression du phénomène, nous avons calculé qu'elles devraient être, pour les expériences précitées, les densités correspondant à une valeur de n plus grande ou plus petite d'un dixième d'unité, ce qui conduit au tableau suivant :—¹

Longueur des tubes	Pressions observées	Densités calculées suivant $e\delta^{1.9}$	Densités calculées suivant $e\delta^2$	Densités calculées suivant $e\delta^{2.1}$
m.	atm.			
60	6	6	6	6
20	10-12	10.7	10.4	10.1
5	23	22.2	20.7	19.6
1.47	38	42.2	38.3	35.1
0.75	50-55	60.1	53.6	48.0
0.42	70-75	81.7	71.7	63.7

On voit que pour les pressions élevées les différences entre les den-

¹ On donne ici les pressions observées, parce que c'est par le moyen des manomètres qu'on a commencé ce travail. Les densités déterminées par la méthode des pesées seront données plus tard.

sités calculées par les formules $e\delta^{1.9}$ et $e\delta^{2.1}$ et l'observation se prononcent assez pour qu'on doive les rejeter.

C'est donc bien la formule $e\delta^2$ qui représente le phénomène, c'est-à-dire, que l'action du gaz oxygène pour les bandes (nous avons donné les nombres pour la bande près de D, mais les autres bandes étudiées conduisent à la même loi) est, pour une même épaisseur, proportionnelle au carré de la densité.

Armé de cette connaissance de la loi, nous allons reprendre l'étude de l'atmosphère terrestre, non-seulement afin de voir si la difficulté qui nous avait arrêtés se trouve levée, mais même pour y chercher une confirmation de la loi.

Cherchons d'abord, d'après la loi du carré de la densité, quelle soit l'action de l'atmosphère sur un faisceau de lumière qui la traverse normalement.

Soit A B une colonne d'air considérée dans l'atmosphère; m m' une tranche infiniment mince à la hauteur H; δ la densité de l'atmosphère en ce point.

La force d'absorption F aura pour différentielle

$$dF = -\delta^2 dH.$$

Mais la densité δ est proportionnelle à la pression barométrique h ou à $\delta = Kh$

$$\text{et } dF = -K^2 h^2 dH.$$

Cette équation intégrée, de $h=0$ à $h=760$ et en remarquant que $K = \frac{1}{760}$ et prenant $dH = -18336 \log e \frac{dh}{h}$, conduit à la valeur

$$F = 3981^m.$$

Mais ce résultat suppose l'atmosphère entièrement formée d'oxygène à la densité de l'air; l'oxygène n'en représente que le cinquième, ou plutôt le 0.208, dont le carré est 0.043; il faut multiplier par ce nombre et on a $F = 172^m$.

Ainsi l'action de l'atmosphère sur un faisceau qui la traverse normalement équivaut à celle d'une colonne d'oxygène de 172 mètres environ à la pression d'une atmosphère.

Or, notre tube de 60 mètres commençant à donner les bandes à la pression de 6 atmosphères est équivalent d'après la loi du carré à $60 \times 6^2 = 2160$ mètres d'oxygène à la même pression, c'est-à-dire, que le tube équivaut dans ces conditions à plus de douze fois l'action de l'atmosphère.

Nous avons maintenant l'explication péremptoire de l'absence des bandes dans le spectre solaire pendant le milieu de la journée.

Mais quand le soleil est abaissé sur l'horizon ses rayons traversent alors des épaisseurs atmosphériques qui peuvent devenir considérables et équivaloir et au delà les actions naissantes constatées dans nos tubes.

On retrouve, en effet, dans le spectre du soleil levant ou couchant, les bandes que nous avons décrites, et quand l'astre est à l'horizon, et surtout quand il est au-dessous, plusieurs de ces bandes acquièrent une extrême intensité.

Le spectre solaire en présente d'autres qui appartiennent également à l'oxygène, mais la présente étude ne porte que sur les trois bandes dont nous avons parlé et dont la considération est suffisante pour asseoir la loi.

Puisque l'atmosphère dans des circonstances favorables peut donner naissance au phénomène dont nous cherchons la loi, nous devons la faire pour en obtenir une nouvelle confirmation—confirmation qui sera précieuse parce qu'elle regarde les basses pressions, depuis la densité nulle jusqu'à un cinquième d'atmosphère environ.

Dans ce but nous avons institué une série d'observations du spectre solaire soit par l'examen optique, soit par la photographie.

Ces études ont été poursuivies à Meudon, aux Alpes, et à l'observatoire du Pic du Midi.

La bande du rouge et celle du jaune près de D sont déjà nettement visibles quand le soleil est à plusieurs degrés au-dessus de l'horizon. Celle du bleu près de F demande une épaisseur atmosphérique traversée beaucoup plus grande. Je l'ai obtenue photographiquement et assez forte au Pic du Midi avec le soleil abaissé d'un à deux degrés au-dessous de l'horizon.

Pour la vérification précise de la loi il faut calculer d'abord par une formule générale les actions subies d'après cette loi par un rayon lumineux qui traverse l'atmosphère suivant une direction déterminée, et chercher ensuite quel angle le rayon doit faire avec la verticale pour subir une action équivalente à celle, par exemple, du tube de 60 mètres chargé d'oxygène à 6 atmosphères, lequel donne, comme on sait, la bande de D naissante.

Cette hauteur du soleil déterminée, il faut obtenir une série de spectres solaires comparables à ceux des tubes et correspondant à des hauteurs progressives et déterminées du soleil, et dans cette série chercher la hauteur pour laquelle la bande en question est évanouissante.

Cette recherche a été faite, mais les calculs ne sont pas encore terminés; nous pouvons dire seulement que la loi y trouve une nouvelle confirmation.

Mais cette loi a reçu dernièrement une confirmation inattendue d'une expérience sur l'oxygène liquide de M. Olszewski, si cette expérience est exacte. M. Olszewski, en liquéfiant l'oxygène, a annoncé qu'il avait constaté la présence des bandes dont j'ai annoncé l'existence avec une épaisseur de liquide de 7 millimètres environ. Or, si nous admettons, comme on le fait généralement, pour la densité de l'oxygène liquide une densité très voisine de celle de l'eau, nous trouverons que cette densité serait 695 fois plus grande que celle de l'oxygène à la densité correspondante à une atmosphère.

On a en conséquence :

$$60 \times \bar{6}^2 = x \cdot \overline{695}^2$$

$$x = \frac{60 \cdot \bar{6}^2}{\overline{695}^2} = 0^m.0045 ;$$

c'est-à-dire, que la bande de D serait naissante pour une épaisseur de 4.5^{mm} d'oxygène gazeux ayant cette densité.

Or, si la bande est naissante pour $4\frac{1}{2}$ mm elle doit être accusée pour 7mm, et c'est ce que M. Olszewski annonce avoir trouvé.

Dans ce travail nous avons parlé seulement de la bande près de D, mais la loi en question se vérifie également pour les bandes du rouge et du bleu que nous avons considérées

Ainsi cette loi se trouve actuellement vérifiée depuis une densité nulle de l'oxygène jusqu'à celle qui égale celle de l'eau, c'est-à-dire, entre les termes les plus extrêmes qu'on puisse considérer.

Le groupe de la raie B qui se résout en raies paraît suivre, au contraire, la loi générale de la proportionnalité du produit de l'épaisseur traversé par la densité.

Nous nous en sommes assurés jusqu'à 100 atmosphères.

Il convient de faire remarquer les horizons que cette loi nouvelle du carré ouvre en analyse spectrale et en mécanique moléculaire. Pour nous elle ne représente que le début des études qui auront pour objet la constitution moléculaire des corps par les actions que ces corps exercent sur la lumière quand on les soumet à l'action de forces variées.

Pour l'oxygène notamment elle nous fait soupçonner que la constitution moléculaire de ce corps n'est pas simple et qu'il y a lieu de faire de nouvelles recherches à cet égard.

TRANSACTIONS OF THE SECTIONS.

TRANSACTIONS OF THE SECTIONS.

SECTION A.—MATHEMATICAL AND PHYSICAL SCIENCE.

PRESIDENT OF THE SECTION—Professor G. F. FITZGERALD, M.A., F.R.S.

THURSDAY, SEPTEMBER 6.

The PRESIDENT delivered the following Address:—

THE British Association in Bath, and especially we here in Section A, have to deplore a very great loss. We confidently anticipated profit and pleasure from the presence in this chair of one of the leading spirits of English science, Dr. Schuster. We deplore the loss and we deplore the cause of it. It is always sad when want of strength makes the independent dependent, and it is doubly sad when a life's work is thereby delayed; and to selfish humanity it is trebly sad when, as in this case, we ourselves are involved in the loss. And our loss is great. Dr. Schuster has been investigating some very important questions. He has been studying electric discharges in gases, and he has been investigating the probably allied question of the variations of terrestrial magnetism. We anticipated his matured pronouncements upon these subjects, and also the advantage of his very wide general information upon physical questions, and the benefit of his judicial mind while presiding here.

As to myself, his substitute, I cannot express how much gratified I feel at the distinguished honour done me in asking me to preside. It has been one of the ambitions of my life to be worthy of it, and I will do my best to deserve your confidence; man can do no more, and upon such a subject 'the less said the soonest mended.'

I suppose most former occupants of this chair have looked over the addresses of their predecessors to see what sort of a thing was expected from them. I find that very few had the courage to deliver no address. Most have devoted themselves to broad general questions, such as the relations of mathematics to physics, or more generally deductive to inductive science. On the other hand, several have dealt each with his own speciality. On looking back over these addresses my attention was specially arrested by the first two past presidents of this section, whose bodily presence we cannot have here. They were presidents of Section A in consecutive years. In 1874 Provost Jellett occupied this chair, and in 1875 Professor Balfour Stewart occupied it. Both have gone from us since the last meeting of this Association. Each gave a characteristic address. The Provost, with the clearness and brilliancy that distinguished his great intellect, plunged through the deep and broad questions surrounding the mechanism of the universe, and with impassioned earnestness claimed on behalf of science the right to prosecute its investigations until it attains, if it ever does attain, to a mechanical explanation of all things. This intrepid honesty to carry to their utmost the principles of whose truth he was convinced, the utter abhorrence of the shadow of double dealing with truth, was eminently characteristic of one whom all, but especially we of Trinity College,

Dublin, will long miss as a lofty example of the highest intellectual keenness and honesty, and mourn as the truest-hearted friend, full of sympathy and Christian charity. In 1875 Professor Stewart gave us a striking example of the other class of address in a splendid exposition of the subject he did so much to advance, namely, solar physics. He brought together from the two great storehouses of his information and speculation a brilliant store, and displayed them here for the advancement of science. Him, too, all science mourns. Though, from want of personal acquaintance, I am unequal to the task of bringing before you his many abilities and great character, you can each compose a fitting epitaph for this well-known great one of British science. In this connection I am only expressing what we all feel when I say how well timed was the royal bounty recently extended to his widow. At the same time the niggardly recognition of science by the public is a disgrace to the enlightenment of the nineteenth century. What chancellor or general with his tens of thousands has done that for his country and mankind that Faraday, Darwin, and Pasteur have done? The 'public' now are but the children of those who murdered Socrates, tolerated the persecution of Galileo, and deserted Columbus.

In a presidential address on the borderlands of the known delivered from this chair the great Clerk Maxwell spoke of as an undecided question whether electro-magnetic phenomena are due to a direct action at a distance or are due to the action of an intervening medium. The year 1888 will be ever memorable as the year in which this great question has been experimentally decided by Hertz in Germany and, I hope, by others in England. It has been decided in favour of the hypothesis that these actions take place by means of an intervening medium. Although there is nothing new about the question, and although most workers at it have long been practically satisfied that electro-magnetic actions are due to an intervening medium, I have thought it worth while to try and explain to others who may not have considered the problem what the problem is and how it has been solved. A presidential address such as this is not for specialists; it is for the whole section; and I would not have thought of dealing with this subject only that its immediate consequences reach to all the bounds of physical science, and are of interest to all its students.

We are all familiar with this, that when we do not know all about something there are generally a variety of explanations of what we do know. Whether there is anything of which there are in reality a variety of explanations is a deep question which some have connected with the Freedom of the Will, but which I am not concerned with here. A notable example of the possibility of a variety of explanations for us is recorded in connection with an incident said to have occurred in the neighbouring town of Clifton, where a remarkable meteorological phenomenon, as it appeared to an observing scientist, was explained by others as a bull's-eye lantern in the hands of Mr. Pickwick. Another kind of example is the old explanation of water rising in a pump, that 'Nature abhors a vacuum,' as compared with the modern one. Nowadays, when we know as little about anything, we say, 'It is the property of electricity to attract.' This is really little or no advance on the old form, and is merely a way of stating that we know a fact but not its explanation. There are plenty of cases still where a variety of explanations is possible. For example, we know of no *experimentum crucis* to decide whether the people I see around me are conscious or are only automata. There are other questions which have existed, but which have been experimentally decided. The most celebrated of these are the questions between the caloric and kinetic theories of heat, and between the emission and undulatory theories of light. The classical experiments by which the case has been decided in favour of the kinetic theory of heat and the undulatory theory of light are some of the most important experiments that have ever been performed. When it was shown that heat disappeared whenever work appeared, and *vice versa*, and so the caloric hypothesis was disproved; when it was shown that light was propagated more slowly in a dense medium than in a rare, the sciences of light and heat were revolutionised. Not but that most who studied the subject had given their adhesion to the true theory before it was finally decided in

general estimation. In fact, Rumford and Davy's experiments on heat, and Young and Fresnell's experiments on light had really decided these questions long before the erroneous views were finally abandoned. I hope that science will not be so slow in accepting the results of experiment in respect of electro-magnetism as it was in the case of light and heat. Rowland's experiment proving an electro-magnetic action between electric charges depending on their absolute and not relative velocities has already proved the existence of a medium relative to which the motion must take place, but the connection is rather metaphysical and is too indirect to attract general attention. The importance of the striking experiments was that they put the language of the wrong hypothesis out of fashion. Elementary text-books that halted between two opinions, and, after the manner of text-books, leant towards that enunciated in preceding text-books, had all perforce to give prominence to the true theory, and the whole rising generation began their researches from a firm and true standpoint. I anticipate the same results to follow Hertz's experimental demonstration of a medium by which electro-magnetic actions are produced. Text-books which have gradually been invoking lines of force, in some respects to the aid of learners and in others to their bewilderment, will now fearlessly discourse of the stresses in the ether that cause electric and magnetic force. The younger generation will see clearly in electro-magnetic phenomena the working of the all-pervading ether, and this will give them a firm and true standpoint for further advances.

And now I want to spend a short time in explaining to you how the question has been decided. An illustrative example may make the question itself clearer, and so lead you to understand the answer better. In colloquial language we say that balloons, hot air, &c., rise because they are light. In old times this was stated more explicitly, and therefore much more clearly. It was said that they possessed a quality called 'levity.' 'Levity' was opposed to 'heaviness.' Heaviness made things tend downwards, levity made things tend upwards. It was a sort of action at a distance. At least it would have required such a hypothesis if it had survived until it was known that heaviness was due to the action of the earth. I expect levity would have been attributed to the direct action of heaven. It was comparatively recently in the history of mankind that the rising of hot air, flames, &c., was attributed to the air. Everybody knew that there was air, but it was not supposed that the upward motion of flames was due to it. We now know that this and the rising of balloons are due to the difference of pressure at different levels in the air. In a similar way we have long known that there is an ether, an all-pervading medium, occupying all known space. Its existence is a necessary consequence of the undulatory theory of light. People who think a little but not much sometimes ask me, 'Why do you believe in the ether? What's the good of it?' I ask them, 'What becomes of light for the eight minutes after it has left the sun and before it reaches the earth?' When they consider that they observe how necessary the ether is. If light took no time to come from the sun there would be no need of the ether. That it is a vibratory phenomenon, that it is affected by matter it acts through—these could be explained by action at a distance very well. The phenomena of interference would, however, require such complicated and curious laws of action at a distance as practically to put such a hypothesis out of court, or else be purely mathematical expressions for wave-propagation. In fact, anything except propagation in time is explicable by action at a distance. It is the same in the case of electro-magnetic actions. There were two hypotheses as to the causes of electro-magnetic actions. One attributed electric attraction to a property of a thing called electricity, to attract at a distance, the other attributed it to a pull exerted by means of the ether, somewhat in the way that air pushes balloons up. We do not know what the structure of the ether is by means of which it can pull, but neither do we know what the structure of a piece of indiarubber is by means of which it can pull, and we might as well ignore the indiarubber, though we know a lot about the laws of its action, because we do not know its structure, as to ignore the ether because we do not know its structure. Anyway, what was wanted was an experiment to decide between the hypothesis of direct action at a distance and of action by means of a medium.

At the time that Clerk Maxwell delivered his address no experiment was known that could decide between the two hypotheses. Specific inductive capacity, the action of intervening matter, the delay in telegraphing, the time propagation of electro-magnetic actions by means of conducting material—these were known, but he knew that they could be explained by means of action at a distance, and had been so explained. Waves in a conductor do not necessarily postulate action through a medium such as the ether. When we are dealing with a conductor and a thing called electricity running over its surface, we are, of course, postulating a medium on or in the conductor, but not outside it, which is the special point at issue. Clerk Maxwell *believed* that just as the same air that transmits sound is able by differences of pressure—i.e., by means of its energy per unit volume—to move bodies immersed in it, so the same ether that transmits light causes electrified bodies to move by means of its energy per unit volume. He believed this, but there was no experiment known then to decide between this hypothesis and that of direct action at a distance. As I have endeavoured to impress upon you, no *experimentum crucis* between the hypotheses is possible except an experiment proving propagation in time either directly, or indirectly by an experiment exhibiting phenomena like those of the interference of light. A theorist may speak of propagation of actions in time without talking of a medium. This is all very well in mathematical formulæ, but, as in the case of light, we must consider what becomes of it after it has left the sun and before it reaches the earth, so every hypothesis assuming action in time really postulates a medium whether we talk about it or not. There are some difficulties surrounding the complete interpretation of some of Hertz's experiments. The conditions are complicated, but I confidently expect that they will lead to a decision on most of the outstanding questions on the theory of electro-magnetic action. However, there is no doubt that he has observed the interference of electro-magnetic waves quite analogous to those of light, and that he has proved that electro-magnetic actions are propagated in air with the velocity of light. By a beautiful device Hertz has produced rapidly alternating currents of such frequency that their wave-length is only about two mètres. I may pause for a minute to call your attention to what that means. These waves are propagated three hundred thousand kilomètres in a second. If they vibrated three hundred thousand times a second the waves would be each a kilomètre long. This rate of vibration is much higher than the highest audible note, and yet the waves are much too long to be manageable. We want a vibration about a thousand times as fast again with waves about a mètre long. Hertz produced such vibrations, vibrating more than a hundred million times a second. That is, there are as many vibrations in one second as there are seconds—in a day? No, far more. In a week? No, more even than that. The pendulum of a clock ticking seconds would have to vibrate for four months before it would vibrate as often as one of Hertz's vibrators vibrates in one second. And how did he detect the vibrations and their interference? He could not see them; they are much too slow for that; they should go about a million times as fast again to be visible. He could not hear them; they are much too quick for that. If they went a million times more slowly they would be well heard. He made use of the principle of resonance. You all understand how by a succession of well-timed small impulses a large vibration may be set up. It explains many things, from speech to spectrum analysis. It is related that a former Marquess of Waterford used the principle to overturn lamp-posts; his ambition soared above knocker-wrenching. So that it is a principle known to others besides scientific men. Hertz constructed a circuit whose period of vibration for electric currents was the same as that of his generating vibrator, and he was able to see sparks, due to the induced vibration, leaping across a small air-space in this resonant circuit. The well-timed electrical impulses broke down the air-resistance just as those of my Lord of Waterford broke down the lamp-post. The combination of a vibrating generating circuit with a resonant-receiving circuit is one that I spoke of at the meeting of the British Association at Southport as one by which this very question might be studied. At the time I did not see any feasible way of detecting the induced resonance; I did not anticipate that it could

produce sparks. By its means, however, Hertz has been able to observe the interference between waves incident on a wall and the reflected waves. He placed his generating vibrator several wave-lengths away from a wall, and placed the receiving resonant circuit between the generator and the wall, and in this air-space he was able to observe that at some points there were hardly any induced sparks, but at other and greater distances from his generator they reappeared to disappear again in regular succession at equal intervals between his generator and the wall. It is exactly the same phenomenon as what are known as Lloyd's bands in optics, which are due to the interference between a direct and a reflected wave. It follows hence that, just as Young's and Fresnell's researches on the Interference of Light prove the undulatory theory of optics, so Hertz's experiment proves the ethereal theory of electro-magnetism. It is a splendid result. Henceforth I hope no learner will fail to be impressed with the theory—hypothesis no longer—that electro-magnetic actions are due to a medium pervading all known space, and that it is the same medium as the one by which light is propagated, that non-conductors can, and probably always do, as Professor Poynting has taught us, transmit electro-magnetic energy. By means of variable currents energy is propagated into space with the velocity of light. The rotation of the earth is being slowly stopped by the diurnal rotation of its magnetic poles. This seems a hopeful direction in which to look for an explanation of the secular precession of terrestrial magnetism. It is quite different from Eddlund's curious hypothesis that free space is a perfect conductor. If this were true, there would be a pair of great antipoles outside the air, and terrestrial magnetism would not be much like what it is, and I think the earth would have stopped rotating long ago. With alternating currents we *do* propagate energy through non-conductors. It seems almost as if our future telegraph cables would be pipes. Just as the long sound waves in speaking tubes go round corners, so these electro-magnetic waves go round corners if they are not too sharp. Professor Lodge will probably have something to tell us on this point in connection with lightning conductors. The silvered glass-bars used by surgeons to conduct light are exactly what I am describing. They are a glass, a non-conducting, and therefore transparent, bar surrounded by a conducting, and therefore opaque, silver sheath, and they transmit the rapidly alternating currents we call light. There would not be the same difficulty in utilising the energy of these electro-magnetic waves as in utilising radiant heat. Having all the vibrations of the same period we might utilise Hertz's resonating circuits, and in any case the second law of thermodynamics would not trouble us when we could practically attain to the absolute zero of these, as compared with heat, long-period vibrations.

We seem to be approaching a theory as to the structure of the ether. There are difficulties from diffusion in the simple theory that it is a fluid full of motion, a sort of vortex sponge. There were similar difficulties in the wave theory of light owing to wave propagation round corners, and there is as great a difficulty in the jelly theory of the ether arising from the freedom of motion of matter through it. It may be found that there is diffusion or it may be found that there are polarised distributions of fluid kinetic energy which are not unstable when the surfaces are fixed; more than one such is known. Osborne Reynolds has pointed out another, though in my opinion less hopeful, direction in which to look for a theory of the ether. Hard particles are abominations. Perhaps the impenetrability of a vortex would suffice. Oliver Lodge speaks confidently of a sort of chemical union of two opposite kinds of elements forming the ether. The opposite sides of a vortex ring might perchance suit, or maybe the ether, after all, is but an atmosphere of some infra-hydrogen element: these two latter hypotheses may both come to the same thing. Anyway we are learning daily what sort of properties the ether must have. It must be the means of propagation of light; it must be the means by which electric and magnetic forces exist; it should explain chemical actions and, if possible, gravity.

On the vortex-sponge theory of the ether there is no real difficulty by reason of complexity why it should not explain chemical actions. In fact, there is every reason to expect that very much more complex actions would take place at distances

comparable with the size of the vortices than at the distances at which we study the simple phenomena of electro-magnetism. Indeed, if vortices can make a small piece of a strong elastic solid we can make watches and build steam engines and any amount of complex machinery, so that complexity can be no essential difficulty. Similarly the instantaneous propagation of gravity, if it exists, is not an essential difficulty, for vortices each occupy all space, and they act on one another simultaneously everywhere. The theory that material atoms are simple vortex rings in a perfect liquid otherwise unmoving is insufficient, but with the innumerable possibilities of fluid motion it seems almost impossible but that an explanation of the properties of the universe will be found in this conception. Anything purporting to be an explanation founded on such ideas as 'an inherent property of matter to attract,' or building up big elastic solids out of little ones, is not of the nature of an ultimate explanation at all; it can only be a temporary stopping-place. There are metaphysical grounds, too, for reducing matter to motion and potential to kinetic energy.

These ideas are not new, but it is well to enunciate them from time to time, and a presidential address in Section A is a fitting time. Besides all this it has become the fashion to indulge in quaint cosmical theories and to dilate upon them before learned societies and in learned journals. I would suggest, as one who has been bogged in this quagmire, that a successor in this chair might well devote himself to a review of the cosmical theories propounded within the last few years. The opportunities for piquant criticism would be splendid.

Returning to the sure ground of experimental research let us for a moment contemplate what is betokened by this theory that in electro-magnetic engines we are using as our mechanism the ether, the medium that fills all known space. It was a great step in human progress when man learnt to make material machines, when he used the elasticity of his bow and the rigidity of his arrow to provide food and defeat his enemies. It was a great advance when he learnt to use the chemical action of fire; when he learnt to use water to float his boats and air to drive them; when he used artificial selection to provide himself with food and domestic animals. For two hundred years he has made heat his slave to drive his machinery. Fire, water, earth, and air have long been his slaves, but it is only within the last few years that man has won the battle lost by the giants of old, has snatched the thunderbolt from Jove himself and enslaved the all-pervading ether.

The following Report and Papers were read:—

2. *On the Behaviour of Water under great Provocation from Heat.*
By Professor W. RAMSAY, F.R.S.
3. *On the Proof of the Logarithmic Law of Atomic Weights.*
By Dr. G. JOHNSTONE STONEY, F.R.S.
4. *On the Oscillations of a Rotating Liquid Spheroid and the Genesis of the Moon.* By A. E. H. LOVE, B.A.

Riemann's investigations of the motion of a liquid ellipsoid¹ contain the condition of stability of the form of steady motion, usually referred to as 'Maclaurin's spheroid,' when the liquid is perfectly inviscid. The equation for the critical value of the eccentricity of the spheroid is—

$$e(3 + 4e^2) \sqrt{1 - e^2} = (3 + 2e^2 - 4e^4) \sin^{-1}e,$$

¹ *Abh. Kön. Ges. Wiss. Göttingen*, 1860.

or, taking the notation of Thomson and Tait, in which $(1+f^2)(1-e^2)=1$, the critical value of f is nearly equal to 3.14. If f be greater than this value, the motion is unstable. Also M. Poincaré¹ has proved the statement of Thomson and Tait that the motion is secularly unstable for any degree of viscosity, however small, when f exceeds 1.39457, and he has shown that it is thoroughly stable for all displacements when f is less than this value.

In this paper Riemann's equations of motion are applied to find the small oscillations of a perfectly inviscid spheroidal mass of liquid, rotating as if rigid about its polar axis, whose direction is fixed in space, the displacement contemplated being of such a kind that the bounding surface remains ellipsoidal. It appears that there are two periods of oscillation, viz.: if $n/2\pi$ be the frequency, we have either

$$n^2 = 16\pi\gamma\rho/(3+f^2) - 2\omega^2(3+8f^2+f^4)/(3f^2+f^4),$$

or
$$n^2 = 24\pi\gamma\rho(1+f^2)/(3+f^2) - \omega^2(1+f^2)(27+18f^2-f^4)/(3+f^2)^2,$$

where ρ is the density of the spheroid, ω the angular velocity, and γ the constant of gravitation. In these ω and f are connected by the condition of steady motion, viz.:—

$$(3+f^2)\tan^{-1}f = f(3 + \omega^2 f^2 / 2\pi\gamma\rho).$$

These values of n vary very little for different small values of ω , so that for a spheroid rotating in any period longer than about three hours the period varies very nearly inversely as the square root of the density.

The determination of these periods of oscillation has an important bearing on the question of the origin of the moon. Professor Darwin in his paper on the 'Precession of a Viscous Spheroid and the Remote History of the Earth'² saw reason to reject Laplace's hypothesis that the moon separated from the earth as a ring because the angular velocity was too great for stability. In the light of Riemann's and Poincaré's researches, above referred to, it is clear that, when the density is not less than 3, and the period of rotation longer than three hours, the motion is certainly stable. According to Professor Darwin, the period of rotation of the earth-moon system when the two bodies formed a single rotating mass may be estimated at something between two and six hours (more probably between two and four hours),³ so that, even allowing for continued contraction of the two cooling bodies, and remembering that the present mean density of the moon is about 3.7, it seems highly improbable that Laplace's hypothesis as to instability can be correct. Professor Darwin suggested as one alternative that possibly the spheroid might have a period of free oscillation not far removed from the semi-diurnal tidal period, in which case the solar tides would be of enormous height, and we should not then have to make additional demands on the lapse of time with a view to the consolidation of the ring-moon into one body.

Now it is shown in this paper that with a density of 5.67 the longer period is very nearly equal to $1\frac{1}{2}$ hours, while with a density of 3 this period is very nearly equal to two hours, whatever the rate of rotation may be, provided that it is not faster than once in three hours; so that, if the period of rotation ever came to be between three and four hours, the density may easily have been such as to make the period of free oscillation very nearly identical with that of the semi-diurnal solar tides. Thus the possibility of Professor Darwin's guess is confirmed.

5. *Waves in a Viscous Liquid.*⁴ * By A. B. BASSET, M.A.

The propagation of waves in a viscous liquid was first considered by Professor Stokes,⁵ who showed that when the viscosity is small, and the depth of the liquid

¹ *Acta Mathematica*, vii. 1885.

² *Phil. Trans.* 1879.

³ 'On the Secular Changes in the Elements of the Orbit of a Satellite,' § 22, *Phil. Trans.* 1880.

⁴ The original paper is published in the author's treatise on *Hydro-dynamics*, vol. ii. §§ 519-523.

Trans. Camb. Phil. Soc. vol. ix.

so great that it may be treated as infinite, the motion is represented by a harmonic function whose amplitude diminishes as the time increases. Professor Stokes' result was obtained by means of the dissipation function; and the object of the present paper is to solve the problem by a direct process, which possesses the advantage of furnishing a result which is applicable to highly viscous as well as to slightly viscous liquids, and also to solve the same problem when the depth of the liquid is finite.

In order to solve the problem of deep sea waves we must find a solution, representing wave motion, of the equation

$$\nabla^2(\nabla^2 - \nu^{-1}d/dt)\psi = 0 \quad . \quad . \quad . \quad . \quad . \quad (1)$$

where ψ is Earnshaw's current function, and which also satisfies the conditions that the tangential and normal stresses at the free surface are zero. Measuring the axis of x in the direction of propagation of the waves, we assume that x and t enter in the form of the exponential factor e^{imx+kt} , and the principal object of the investigation is to find the equation for determining k . This equation is

$$k^2 + 4m^2k\nu + gm + 4m^4\nu^2 - 4m^3\nu^2a = 0 \quad . \quad . \quad . \quad . \quad . \quad (2)$$

$$\text{where} \quad a^2 = m^2 + k/\nu \quad . \quad . \quad . \quad . \quad . \quad (3)$$

When ν is small, as in the case of water,

$$k = -2m^2\nu \pm \sqrt{(4m^4\nu^2 - gm)} \quad . \quad . \quad . \quad . \quad . \quad (4)$$

$$= -2m^2\nu \pm in \quad . \quad . \quad . \quad . \quad . \quad (5)$$

approximately, where $n^2 = gm$; which represents a train of waves whose velocity of propagation is slightly less than $(g\lambda/2\pi)^{1/2}$, and whose modulus of decay is $\lambda^2/8\pi^2\nu$, where λ is the wave length.

If, however, ν is large, we shall obtain

$$k/\nu = -m^2 \times .92 \quad . \quad . \quad . \quad . \quad . \quad (6)$$

approximately, which shows that the value of k is real and negative; hence the motion is non-periodic, and rapidly subsides.

When the depth of the liquid is finite and equal to h , the equation for k is a rather complicated transcendental one, which is expressible in the form of a determinant of four rows. If, however, ν is small, it is reducible to a quadratic whose roots are

$$k = -2m^2\nu \pm i(mg \tanh mh)^{1/2} \quad . \quad . \quad . \quad . \quad . \quad (7)$$

which is the approximate solution of the problem.

This represents a train of waves whose velocity of propagation is

$$(g\lambda/2\pi \cdot \tanh 2\pi h/\lambda)^{1/2},$$

and whose modulus of decay is $\lambda^2/8\pi^2\nu$.

6. *On a Hydrostatic Balance.*¹ By J. JOLY, M.A., B.E.

7. *On the Meldometer.* By J. JOLY, M.A., B.E.

This is an apparatus enabling mineralogists to compare the melting-points of minerals and observe their behaviour at very high temperatures. It is applicable for dealing with very small quantities of bodies. The apparatus consists essentially of a ribbon of thin platinum, about 4 cm. long by 3 mm. wide, clamped in two forceps with attached binding screws, so that a current from a small storage cell, or two or three Grove's cells, may be passed through it. The apparatus rests on the stage of the microscope, the fragments of mineral being laid on the platinum strip and observed with a one-inch objective. A resistance, of simple construction, which can be set to automatically diminish or increase at any desired rate is placed

¹ An account of this apparatus appears in the *Philosophical Magazine* for September 1888, p. 26.

in circuit. As this resistance diminishes the temperature of the strip rises, so that the operator may confine his attention to the observation of the bodies on the platinum hob, while they are being exposed to a temperature gradually increasing up to that of the melting-point of platinum. Quartz is melted by this apparatus, and orthoclase caused to boil. Many substances are decomposed displaying characteristic phenomena. It reveals that the order of melting-points set forth in von Kobell's scale is incorrect.

Another form of the apparatus, not yet completed, will permit, it is hoped, of an approximate estimation of the temperature of the platinum hob at any moment.

8. *Electro-calorimetry.* By Professor WILLIAM STROUD, B.A., D.Sc.,
and W. W. HALDANE GEE, B.Sc.

During the year experiments have been continued both at Owens College, Manchester, and Yorkshire College, Leeds, with the null method described at the last British Association meeting. Important improvements have been effected in the details of the method and apparatus used. The calorimeters are now made in the form of barrels closed by screw plugs which effectually prevent leakage and loss by evaporation. For agitation of the contents of the calorimeters paddles and plungers worked by electro-motor or clockwork have been entirely discarded in favour of the simple method of rocking or shaking by hand the calorimeters themselves. For the heating coils platinoid wire has been found the best, each coil being formed of a number of strands of fine wire well insulated by silk and paraffin. Experiments made with the bolometer have shown that, compared with the thermo-pile, it is greatly inferior to the latter for the purpose of ascertaining the equality of temperature of the calorimeters. A number of determinations have been made which confirm the accuracy of the method.

9. *On Figures produced by Electric Action on Photographic Dry Plates.*¹
By J. BROWN.

A rapid bromide photographic dry plate is laid film side up on a sheet of metal in connection with one terminal of a good induction coil. A wire from the other terminal is brought down on the centre of the film. A single discharge from the coil is given, and the plate developed in the usual way.

If the wire touching the film be the negative pole, a beautiful figure with branches carrying palm-like fronds is produced; if positive a number of irregular branches of a quite different character accompanied by a quantity of light radiating irregular tracery extending beyond the darker branches.

If the discharge take place with the two poles of the coil touching the uncoated side of the plate, other figures are produced by the electricity induced on the film, the positive and negative differing both from each other, and from those given as described above by the discharge on the film.

If a coating of tinfoil be placed on each side of the plate, after the manner of a Franklin's pane, that on the film having letters cut out like a stencil plate, the result after electrification of the foils and development is a dark irregular marking round the edge of the stencil plate foil on the film, including the edges of the cut-out parts, apparently produced by a discharge from the edge, together with irregular blotchings, apparently corresponding to wrinkles in the foil. If a piece of gutta-percha tissue be placed between the foil and the film, the effect is much the same. If four thicknesses intervene there is only irregular blotching without any appearance of the outline of the letters cut in the foil.

These last effects, together with some peculiarities of the figures produced by the discharge on the film itself, appear to show that the figures are produced, partly at least, by a direct action of the electricity on the film without the intervention of light or purely photo-chemical causes as usually understood. Further

¹ *Phil. Mag.* Dec. 1888.

investigation may show that we have here a new kind of experimental evidence on the relations of electricity and light.

10. *Comparison of Gassner's Dry Cells with Leclanché's.*

By WM. LANT CARPENTER.

Two Gassner's cells were examined, the round form having an E.M.F. of 1.317^v and an internal resistance of 0.205^Ω, the measurements of flat form being 1.52^v and 0.700^Ω. The E.M.F.'s were measured by Law's condenser method, and the internal resistance by Kempe's method, the shunt employed being 1^Ω.

The resistance of a ringing bell, measured by the reproduced deflection method, was found to be 20^Ω. The two dry cells and a No. 2 size Leclanché were separately circuited for 168 hours through 20^Ω, and observations of the potential differences were made at frequent intervals. Similar observations were made during the recovery from the polarisation thus produced, and the results were plotted in curves, which were exhibited. The round dry cell was circuited through 3^Ω for 5½ hours, the potential differences and internal resistances being measured at intervals so that the current might be calculated.

From the results obtained it appeared that the round form of dry cell polarised less than a No. 2 Leclanché, but took longer to recover when the circuit was opened, and its internal resistance was considerably lower, but that the flat form polarised in most cases more than a No. 2 Leclanché, and had the same internal resistance.

11. *On the Intensity of Magnetisation of soft Iron Bars of various lengths in a uniform Magnetic Field.* By A. TANAKADATÉ.

Experiments were made on bars for which the ratio of length to diameter varied from 13 to 32; the bars were subjected to different strengths of magnetising fields, and the magnetic moments thereby acquired were measured, the mean intensity of magnetisation being then calculated. The results agreed with those of Professor Ewing on bars, for which the above ratio varied from 50 to 300.

Mention is made also of some experiments by the author in 1883 wherein a magnetic field of constant strength was used to act on a mass of iron that was varied by steps. The mass consisted of iron wires, which were varied in number. With a field of 46 C.G.S. units the magnetometer deflection was sensibly proportional to the number of wires up to 10; as the number of wires was increased the ratio of deflection to number diminished, the maximum deflection practically occurring with 25 wires, no greater deflection occurring with 41 wires. When the wires numbered more than 10, some of them would be thrown out of the bundle, requiring pressure to keep them in the solenoid, though the whole bundle could with care be so placed that no wire would jump out. Each wire was obviously in an unstable state of equilibrium, being under the action of opposed forces, one from the solenoid tending to throw it out, and the other from its fellow wires tending to eject it.

FRIDAY, SEPTEMBER 7.

The following Papers were read:—

1. *Recent Progress in the Use of Concave Gratings for Spectrum Analysis.* By Professor H. A. ROWLAND.
2. *Is the Velocity of Light in an Electrolytic Liquid influenced by an Electric Current in the direction of propagation?* By Lord RAYLEIGH, LL.D., Sec. R.S.—See Reports, p. 341.

3. *On the Measurement of the Length of Electro-magnetic Waves.*

By Professor OLIVER J. LODGE, F.R.S.

The author has been endeavouring to manufacture light by direct electric action without the intervention of heat, utilising for the purpose Maxwell's theory that light is really an electric disturbance or vibration.

The means adopted is the oscillatory discharge of a Leyden jar whose rate of vibration has been made as high as 100 million complete vibrations per second.

The waves so obtained are about three yards long, and are essentially light in every particular except that they are unable to affect the retina. To do this they must be shortened to the hundred-thousandth of an inch. All that has yet been accomplished, therefore, is the artificial production of direct electrical radiation differing in no respect from the waves of light except in the one matter of length.

The electrical waves travel through space with the same speed as light, and are refracted and absorbed by material substances according to the same laws. It only wants to be able to generate waves of any desired length in order to entirely revolutionise our present best systems of obtaining artificial light by help of steam engines and dynamos, which is a most wasteful and empirical process.

The author measures the waves by converting them into stationary ones by the interference of direct and reflected pulses at the free ends of a long pair of wires attached as appendages to a discharging Leyden-jar circuit. The circuit and its appendages are adjusted till a recoil kick observed at the far end of the wires is a maximum, and the length of each resonant wire is then taken to be half a wave-length. The length so measured agrees with theory.

4. *On the Impedance of Conductors to Leyden-jar Discharges.*

By Professor OLIVER J. LODGE, F.R.S.

In the course of a series of experiments on the theory of lightning-conductors the author had devised an arrangement for testing the electromotive force necessary for sending a given discharge through a given conductor, and thus for comparing the obstruction or impedance which various conductors offered to such discharges.

The results were compared with the general theory of Clerk Maxwell and Lord Rayleigh, and were such as entirely to confirm that theory, although at first sight they were paradoxical and surprising.

The apparent resistance was some hundred thousand times greater than would have been obtained for steady currents; and for very high frequencies of alternates, say over a million per second, it was almost independent of the diameter and quite independent of the material of the rod used. In fact, the ordinary laws of conduction fail utterly and a new condition of things obtains.

Iron carries off Leyden-jar discharges quite as well as copper, and apparently in some cases even better. All but this last anomaly are susceptible of complete explanation in the light of the theory of Maxwell and Lord Rayleigh and Mr. Oliver Heaviside, and the experiments verify that theory.

5. *A simple hypothesis for Electro-magnetic Induction of incomplete circuits, with consequent equations of Electric Motion in fixed homogeneous or heterogeneous solid matter.* By Professor Sir WILLIAM THOMSON, LL.D., F.R.S.

1. To avoid mathematical formulas till needed for calculation consider three cases of liquid¹ motion, which for brevity I call Primary, Secondary, Tertiary, defined as follows: Half the velocity in the Secondary agrees numerically and directionally with the magnitude and axis of the molecular spin at the corresponding point of the Primary; or (short, but complete statement) *the velocity in the Secondary is twice the spin in the Primary*; and (similarly) *half the velocity in the Tertiary is the spin in the Secondary*.

¹ I use 'liquid' for brevity to signify incompressible fluid.

2. In the Secondary and Tertiary the motion is essentially without change of density, and in each of them we naturally, therefore, take an incompressible fluid as the substance. The motion in the Primary we arbitrarily restrict by taking its fluid also as incompressible.
